BRN	Branch Never	129
BRSET <i>n</i>	Branch if Bit <i>n</i> in Memory Set	130
BSET <i>n</i>	Set Bit <i>n</i> in Memory	131

BSR	Branch to Subroutine	132
CBEQ	Compare and Branch if Equal	133
CLC	Clear Carry Bit	134
CLI	Clear Interrupt Mask Bit	135
CLR	Clear	136
CMP	Compare Accumulator with Memory	137
COM	Complement (One's Complement)	138
CPHX	Compare Index Register with Memory	139
CPX	Compare X (Index Register Low) with Memory	140
DAA	Decimal Adjust Accumulator	141
DBNZ	Decrement and Branch if Not Zero	143
DEC	Decrement	144
DIV	Divide	145
EOR	Exclusive-OR Memory with Accumulator	146
INC	Increment	147
JMP	Jump	148
JSR	Jump to Subroutine	149
LDA	Load Accumulator from Memory	150
LDHX	Load Index Register from Memory	151
LDX	Load X (Index Register Low) from Memory	152
LSL	Logical Shift Left	153
LSR	Logical Shift Right	154
MOV	Move	155
MUL	Unsigned Multiply	156
NEG	Negate (Two's Complement)	157
NOP	No Operation	158
NSA	Nibble Swap Accumulator	159
ORA	Inclusive-OR Accumulator and Memory	160
PSHA	Push Accumulator onto Stack	161
PSHH	Push H (Index Register High) onto Stack	162
PSHX	Push X (Index Register Low) onto Stack	163
PULA	Pull Accumulator from Stack	164
PULH	Pull H (Index Register High) from Stack	165
PULX	Pull X (Index Register Low) from Stack	166
ROL	Rotate Left through Carry	167
ROR	Rotate Right through Carry	168
RSP	Reset Stack Pointer	169

Table of Contents

RTI	Return from Interrupt	170
RTS	Return from Subroutine	171
SBC	Subtract with Carry	172
SEC	Set Carry Bit	173
SEI	Set Interrupt Mask Bit	174
STA	Store Accumulator in Memory	175
STHX	Store Index Register	176
STOP	Enable $\overline{\text{IRQ}}$ Pin, Stop Oscillator	177
STX	Store X (Index Register Low) in Memory	178
SUB	Subtract	179
SWI	Software Interrupt	180
TAP	Transfer Accumulator to Processor Status Byte	181
TAX	Transfer Accumulator to X (Index Register Low)	182
TPA	Transfer Processor Status Byte to Accumulator	183
TST	Test for Negative or Zero	184
TSX	Transfer Stack Pointer to Index Register	185
TXA	Transfer X (Index Register Low) to Accumulator	186
TXS	Transfer Index Register to Stack Pointer	187
WAIT	Enable Interrupts; Stop Processor	188

1.2 Introduction

The CPU08 is the central processor unit (CPU) of the Motorola M68HC08 Family of microcontroller units (MCU). The fully object code compatible CPU08 offers M68HC05 users increased performance with no loss of time or software investment in their M68HC05-based applications. The CPU08 also appeals to users of other MCU architectures who need the CPU08 combination of speed, low power, processing capabilities, and cost effectiveness.

1.3 Features

CPU08 features include:

- Full object-code compatibility with M68HC05 Family
- 16-bit stack pointer with stack manipulation instructions
- 16-bit index register (H:X) with high-byte and low-byte manipulation instructions
- 8-MHz CPU standard bus frequency
- 64-Kbyte program/data memory space
- 16 addressing modes
- 78 new opcodes
- Memory-to-memory data moves without using accumulator
- Fast 8-bit by 8-bit multiply and 16-bit by 8-bit divide instructions
- Enhanced binary-coded decimal (BCD) data handling
- Expandable internal bus definition for extension of addressing range beyond 64 Kbytes
- Flexible internal bus definition to accommodate CPU performance-enhancing peripherals such as a direct memory access (DMA) controller
- Low-power stop and wait modes

1.4 Programming Model

The CPU08 programming model consists of:

- 8-bit accumulator
- 16-bit index register
- 16-bit stack pointer
- 16-bit program counter
- 8-bit condition code register

See [Figure 2-1. CPU08 Programming Model](#).

1.5 Memory Space

Program memory space and data memory space are contiguous over a 64-Kbyte addressing range. Addition of a page-switching peripheral allows extension of the addressing range beyond 64 Kbytes.

1.6 Addressing Modes

The CPU08 has a total of 16 addressing modes:

- Inherent
- Immediate
- Direct
- Extended
- Indexed
 - No offset
 - No offset, post increment
 - 8-bit offset
 - 8-bit offset, post increment
 - 16-bit offset
- Stack pointer
 - 8-bit offset
 - 16-bit offset
- Relative
- Memory-to-memory (four modes)

Refer to [Section 4. Addressing Modes](#) for a detailed description of the CPU08 addressing modes.

1.7 Arithmetic Instructions

The CPU08 arithmetic functions include:

- Addition with and without carry
- Subtraction with and without carry
- A fast 16-bit by 8-bit unsigned division
- A fast 8-bit by 8-bit unsigned multiply

1.8 Binary-Coded Decimal (BCD) Arithmetic Support

To support binary-coded decimal (BCD) arithmetic applications, the CPU08 has a decimal adjust accumulator (DAA) instruction and a nibble swap accumulator (NSA) instruction.

1.9 High-Level Language Support

The 16-bit index register, 16-bit stack pointer, 8-bit signed branch instructions, and associated instructions are designed to support the efficient use of high-level language (HLL) compilers with the CPU08.

1.10 Low-Power Modes

The WAIT and STOP instructions reduce the power consumption of the CPU08-based MCU. The WAIT instruction stops only the CPU clock and therefore uses more power than the STOP instruction, which stops both the CPU clock and the peripheral clocks. In most modules, clocks can be shut off in wait mode.

2.2 Introduction

This section describes the CPU08 registers.

2.3 CPU08 Registers

Figure 2-1 shows the five CPU08 registers. The CPU08 registers are not part of the memory map.

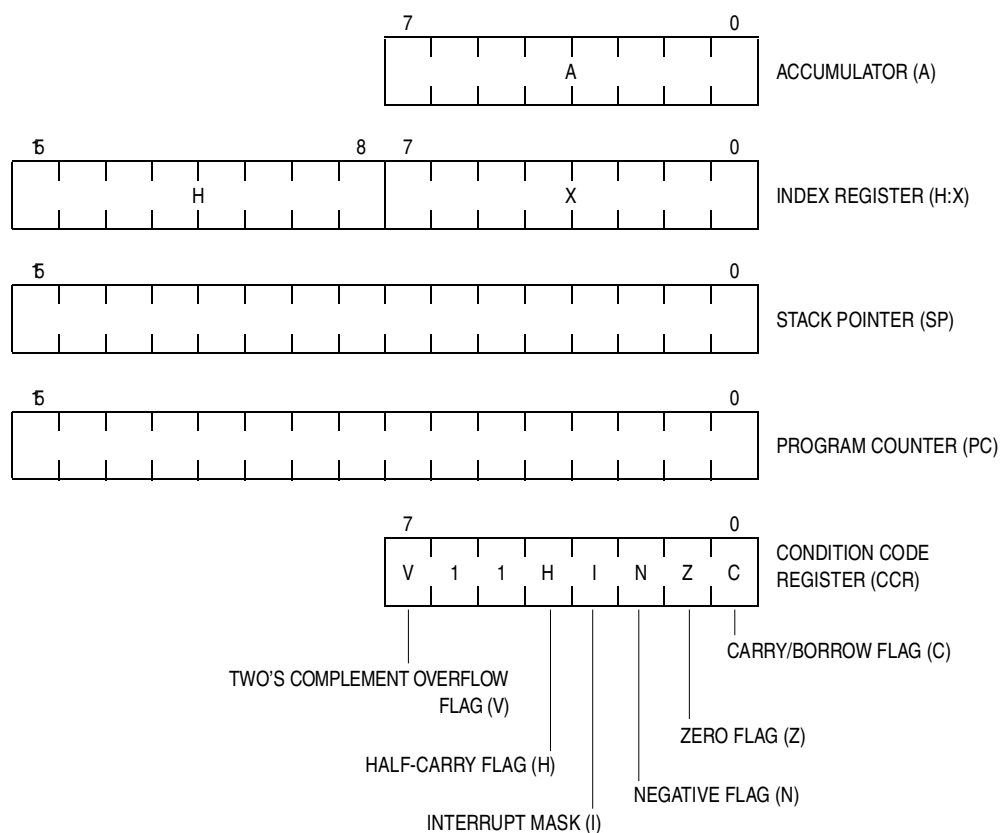

Figure 2-1. CPU08 Programming Model

2.3.1 Accumulator

The accumulator (A) shown in [Figure 2-2](#) is a general-purpose 8-bit register. The central processor unit (CPU) uses the accumulator to hold operands and results of arithmetic and non-arithmetic operations.

Figure 2-2. Accumulator (A)

2.3.2 Index Register

The 16-bit index register (H:X) shown in [Figure 2-3](#) allows the user to index or address a 64-Kbyte memory space. The concatenated 16-bit register is called H:X. The upper byte of the index register is called H. The lower byte of the index register is called X. H is cleared by reset. When H = 0 and no instructions that affect H are used, H:X is functionally identical to the IX register of the M6805 Family.

In the indexed addressing modes, the CPU uses the contents of H:X to determine the effective address of the operand. H:X can also serve as a temporary data storage location. See [4.3.5 Indexed, No Offset](#); [4.3.6 Indexed, 8-Bit Offset](#); and [4.3.7 Indexed, 16-Bit Offset](#).

Figure 2-3. Index Register (H:X)

Architecture

2.3.3 Stack Pointer

The stack pointer (SP) shown in [Figure 2-4](#) is a 16-bit register that contains the address of the next location on the stack. During a reset, the stack pointer is preset to \$00FF to provide compatibility with the M6805 Family.

NOTE: *The reset stack pointer (RSP) instruction sets the least significant byte to \$FF and does not affect the most significant byte.*

The address in the stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack. The SP always points to the next available (empty) byte on the stack.

The CPU08 has stack pointer 8- and 16-bit offset addressing modes that allow the stack pointer to be used as an index register to access temporary variables on the stack. The CPU uses the contents in the SP register to determine the effective address of the operand. See [4.3.8 Stack Pointer, 8-Bit Offset](#) and [4.3.9 Stack Pointer, 16-Bit Offset](#).

Figure 2-4. Stack Pointer (SP)

NOTE: *Although preset to \$00FF, the location of the stack is arbitrary and may be relocated by the user to anywhere that random-access memory (RAM) resides within the memory map. Moving the SP out of page 0 (\$0000 to \$00FF) will free up address space, which may be accessed using the efficient direct addressing mode.*

2.3.4 Program Counter

The program counter (PC) shown in [Figure 2-5](#) is a 16-bit register that contains the address of the next instruction or operand to be fetched.

Normally, the address in the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

During reset, the PC is loaded with the contents of the reset vector located at \$FFFE and \$FFFF. This represents the address of the first instruction to be executed after the reset state is exited.

Figure 2-5. Program Counter (PC)

2.3.5 Condition Code Register

The 8-bit condition code register (CCR) shown in [Figure 2-6](#) contains the interrupt mask and five flags that indicate the results of the instruction just executed. Bits five and six are permanently set to logic 1.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	V	1	1	H	I	N	Z	C
Write:								
Reset:	X	1	1	X	1	X	X	X

X = Indeterminate

Figure 2-6. Condition Code Register (CCR)

V — Overflow Flag

The CPU sets the overflow flag when a two's complement overflow occurs as a result of an operation. The overflow flag bit is utilized by the signed branch instructions:

- Branch if greater than, BGT
- Branch if greater than or equal to, BGE
- Branch if less than or equal to, BLE
- Branch if less than, BLT

This bit is set by these instructions, although its resulting value holds no meaning:

- Arithmetic shift left, ASL
- Arithmetic shift right, ASR
- Logical shift left, LSL
- Logical shift right, LSR
- Rotate left through carry, ROL
- Rotate right through carry, ROR

H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between bits 3 and 4 of the accumulator during an add-without-carry (ADD) or add-with-carry (ADC) operation. The half-carry flag is required for

binary-coded (BCD) arithmetic operations. The decimal adjust accumulator (DAA) instruction uses the state of the H and C flags to determine the appropriate correction factor.

I — Interrupt Mask

When the interrupt mask is set, all interrupts are disabled. Interrupts are enabled when the interrupt mask is cleared. When an interrupt occurs, the interrupt mask is automatically set after the CPU registers are saved on the stack, but before the interrupt vector is fetched.

NOTE: *To maintain M6805 compatibility, the H register is not stacked automatically. If the interrupt service routine uses X (and H is not clear), then the user must stack and unstack H using the push H (index register high) onto stack (PSHH) and pull H (index register high) from stack (PULH) instructions within the interrupt service routine.*

If an interrupt occurs while the interrupt mask is set, the interrupt is latched. Interrupts in order of priority are serviced as soon as the I bit is cleared.

A return-from-interrupt (RTI) instruction pulls the CPU registers from the stack, restoring the interrupt mask to its cleared state. After any reset, the interrupt mask is set and can only be cleared by a software instruction. See [Section 3. Resets and Interrupts](#).

N — Negative Flag

The CPU sets the negative flag when an arithmetic operation, logical operation, or data manipulation produces a negative result.

Z — Zero Flag

The CPU sets the zero flag when an arithmetic operation, logical operation, or data manipulation produces a result of \$00.

C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the carry/borrow flag (as in bit test and branch instructions and shifts and rotates).

2.4 CPU08 Functional Description

This subsection is an overview of the architecture of the M68HC08 CPU with functional descriptions of the major blocks of the CPU.

The CPU08, as shown in [Figure 2-7](#), is divided into two main blocks:

- Control unit
- Execution unit

The control unit contains a finite state machine along with miscellaneous control and timing logic. The outputs of this block drive the execution unit, which contains the arithmetic logic unit (ALU), registers, and bus interface.

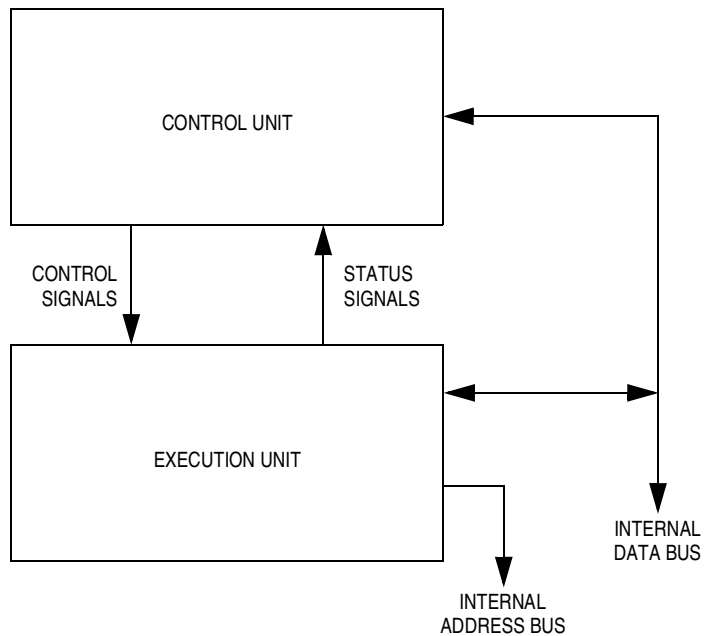

Figure 2-7. CPU08 Block Diagram

2.4.1 Internal Timing

The CPU08 derives its timing from a 4-phase clock, each phase identified as either T1, T2, T3, or T4. A CPU bus cycle consists of one clock pulse from each phase, as shown in **Figure 2-8**. To simplify subsequent diagrams, the T clocks have been combined into a single signal called the CPU clock. The start of a CPU cycle is defined as the leading edge of T1, though the address associated with this cycle does not drive the address bus until T3. Note that the new address leads the associated data by one-half of a bus cycle.

For example, the data read associated with a new PC value generated in T1/T2 of cycle 1 in **Figure 2-8** would not be read into the control unit until T2 of the next cycle.

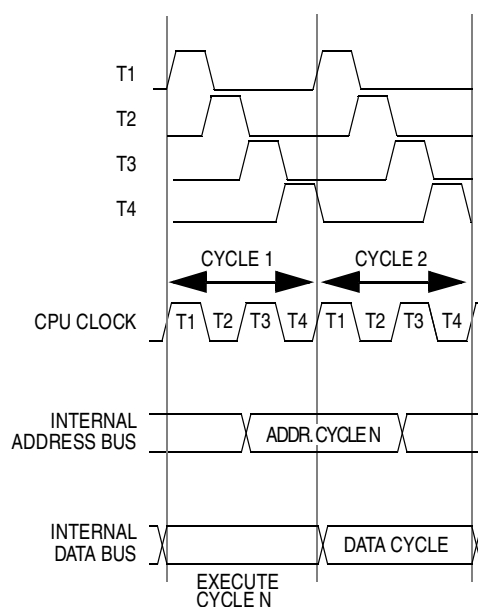

Figure 2-8. Internal Timing Detail

2.4.2 Control Unit

The control unit consists of:

- Sequencer
- Control store
- Random control logic

These blocks make up a finite state machine, which generates all the controls for the execution unit.

The sequencer provides the next state of the machine to the control store based on the contents of the instruction register (IR) and the current state of the machine. The control store is strobed (enabled) when the next state input is stable, producing an output that represents the decoded next state condition for the execution unit (EU). This result, with the help of some random logic, is used to generate the control signals that configure the execution unit. The random logic selects the appropriate signals and adds timing to the outputs of the control store. The control unit fires once per bus cycle but runs almost a full cycle ahead of the execution unit to decode and generate all the controls for the next cycle. The sequential nature of the machine is shown in [Figure 2-9](#).

The sequencer also contains and controls the opcode lookahead register, which is used to prefetch the next sequential instruction. Timing of this operation is discussed in [2.4.4 Instruction Execution](#).

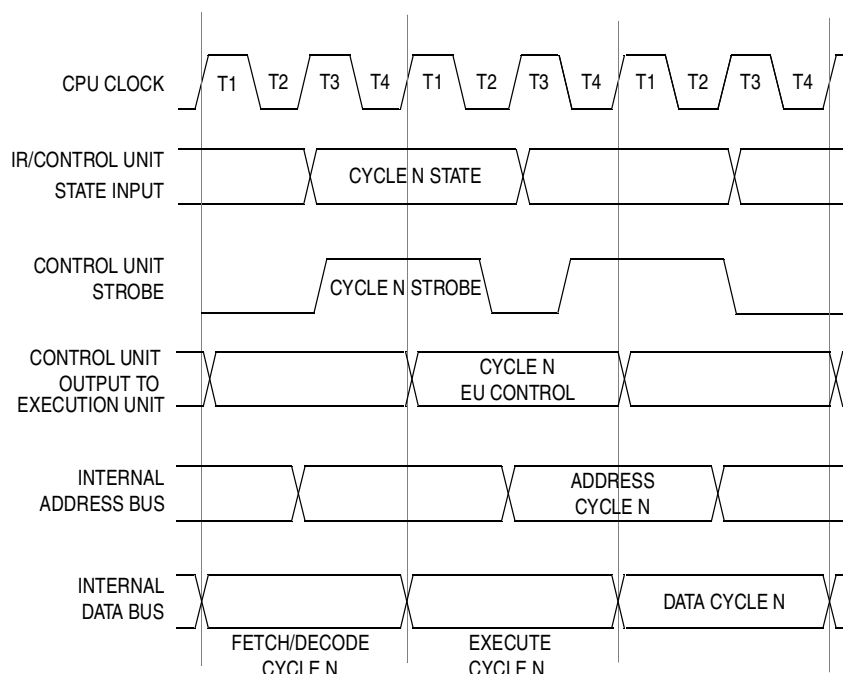

Figure 2-9. Control Unit Timing

2.4.3 Execution Unit

The execution unit (EU) contains all the registers, the arithmetic logic unit (ALU), and the bus interface. Once per bus cycle a new address is computed by passing selected register values along the internal address buses to the address buffers. Note that the new address leads the associated data by one half of a bus cycle. The execution unit also contains some special function logic for unusual instructions such as DAA, unsigned multiply (MUL), and divide (DIV).

2.4.4 Instruction Execution

Each instruction has defined execution boundaries and executes in a finite number of T1-T2-T3-T4 cycles. All instructions are responsible for fetching the next opcode into the opcode lookahead register at some time during execution. The opcode lookahead register is copied into the instruction register during the last cycle of an instruction. This new instruction begins executing during the T1 clock after it has been loaded into the instruction register.

Architecture

Note that all instructions are also responsible for incrementing the PC after the next instruction prefetch is under way. Therefore, when an instruction finishes (that is, at an instruction boundary), the PC will be pointing to the byte **following** the opcode fetched by the instruction. An example sequence of instructions concerning address and data bus activity with respect to instruction boundaries is shown in [Figure 2-10](#).

A signal from the control unit, OPCODE LOOKAHEAD, indicates the cycle when the next opcode is fetched. Another control signal, LASTBOX, indicates the last cycle of the currently executing instruction. In most cases, OPCODE LOOKAHEAD and LASTBOX are active at the same time. For some instructions, however, the OPCODE LOOKAHEAD signal is asserted earlier in the instruction and the next opcode is prefetched and held in the lookahead register until the end of the currently executing instruction.

In the instruction boundaries example ([Figure 2-10](#)) the OPCODE LOOKAHEAD and LASTBOX are asserted simultaneously during TAX and increment INCX execution, but the load accumulator from memory (LDA) indexed with 8-bit offset instruction prefetches the next opcode before the last cycle. Refer to [Figure 2-11](#). The boldface instructions in [Figure 2-10](#) are illustrated in [Figure 2-11](#).

			ORG	\$50

3.2 Introduction

The CPU08 in a microcontroller executes instructions sequentially. In many applications it is necessary to execute sets of instructions in response to requests from various peripheral devices. These requests are often asynchronous to the execution of the main program. Resets and interrupts are both types of CPU08 exceptions. Entry to the appropriate service routine is called exception processing.

Reset is required to initialize the device into a known state, including loading the program counter (PC) with the address of the first instruction. Reset and interrupt operations share the common concept of vector fetching to force a new starting point for further CPU08 operations.

Interrupts provide a way to suspend normal program execution temporarily so that the CPU08 can be freed to service these requests. The CPU08 can process up to 128 separate interrupt sources including a software interrupt (SWI).

On-chip peripheral systems generate maskable interrupts that are recognized only if the global interrupt mask bit (I bit) in the condition code register is clear (reset is non-maskable). Maskable interrupts are prioritized according to a default arrangement. (See [Table 3-2](#) and [3.5.1 Interrupt Sources and Priority](#).) When interrupt conditions occur in an on-chip peripheral system, an interrupt status flag is set to indicate the condition. When the user's program has properly responded to this interrupt request, the status flag must be cleared.

3.3 Elements of Reset and Interrupt Processing

Reset and interrupt processing is handled in discrete, though sometimes concurrent, tasks. It is comprised of interrupt recognition, arbitration (evaluating interrupt priority), stacking of the machine state, and fetching of the appropriate vector. Interrupt processing for a reset is comprised of recognition and a fetch of the reset vector only. These tasks, together with interrupt masking and returning from a service routine, are discussed in this subsection.

3.3.1 Recognition

Reset recognition is asynchronous and is recognized when asserted. Internal resets are asynchronous with instruction execution except for illegal opcode and illegal address, which are inherently instruction-synchronized. Exiting the reset state is always synchronous.

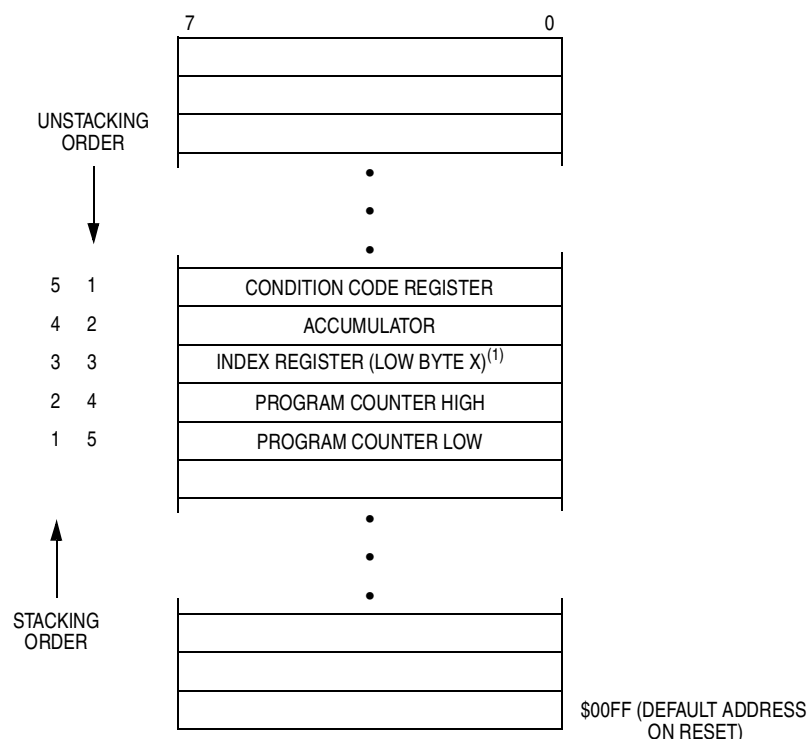

All pending interrupts are recognized by the CPU08 during the last cycle of each instruction. Interrupts that occur during the last cycle will not be recognized by the CPU08 until the last cycle of the following instruction. Instruction execution cannot be suspended to service an interrupt, and so interrupt latency calculations must include the execution time of the longest instruction that could be encountered.

When an interrupt is recognized, an SWI opcode is forced into the instruction register in place of what would have been the next instruction. (When using the CPU08 with the direct memory access (DMA) module, the DMA can suspend instruction operation to service the peripheral.)

Because of the opcode “lookahead” prefetch mechanism, at instruction boundaries the program counter (PC) always points to the address of the next instruction to be executed plus one. The presence of an interrupt is used to modify the SWI flow such that instead of stacking this PC value, the PC is decremented before being stacked. After interrupt servicing is complete, the return-from-interrupt (RTI) instruction will unstack the adjusted PC and use it to prefetch the next instruction again. After SWI interrupt servicing is complete, the RTI instruction then fetches the instruction following the SWI.

3.3.2 Stacking

To maintain object code compatibility, the M68HC08 interrupt stack frame is identical to that of the M6805 Family, as shown in **Figure 3-1**. Registers are stacked in the order of PC, X, A, and CCR. They are unstacked in reverse order. Note that the condition code register (CCR) I bit (internal mask) is not set until after the CCR is stacked during cycle 6 of the interrupt stacking procedure. The stack pointer always points to the next available (empty) stack location.

1. High byte (H) of index register is not stacked.

Figure 3-1. Interrupt Stack Frame

NOTE: *To maintain compatibility with the M6805 Family, H (the high byte of the index register) is not stacked during interrupt processing. If the interrupt service routine modifies H or uses the indexed addressing mode, it is the user's responsibility to save and restore it prior to returning. See [Figure 3-2](#).*

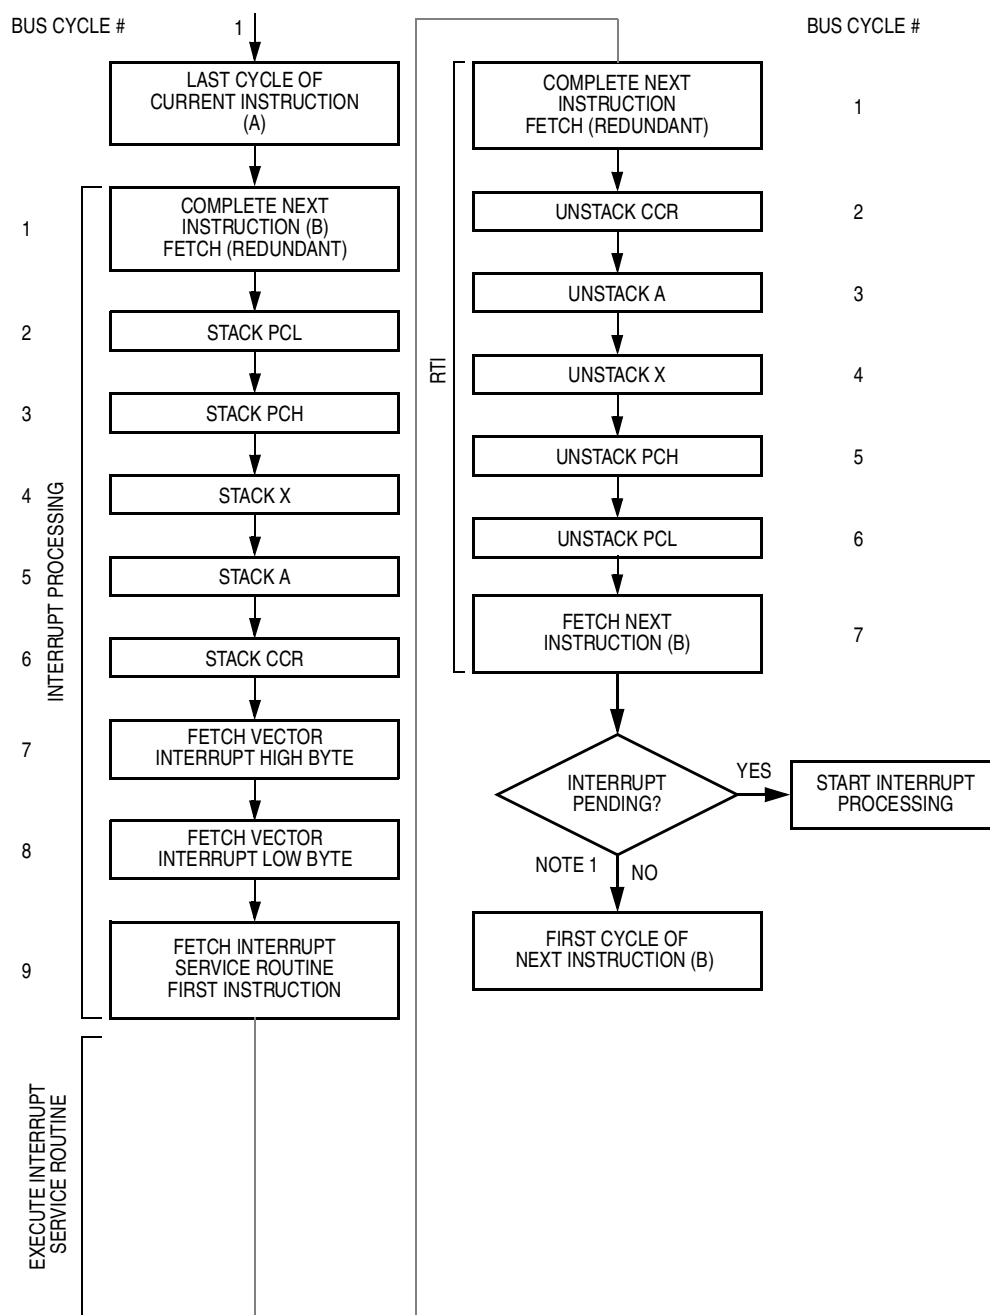

Figure 3-2. H Register Storage

3.3.3 Arbitration

All reset sources always have equal and highest priority and cannot be arbitrated. Interrupts are latched, and arbitration is performed in the system integration module (SIM) at the start of interrupt processing. The arbitration result is a constant that the CPU08 uses to determine which vector to fetch. Once an interrupt is latched by the SIM, no other interrupt may take precedence, regardless of priority, until the latched interrupt is serviced (or the I bit is cleared). See [Figure 3-3](#).

Note 1. Interrupts that occur before this point are recognized.

Figure 3-3. Interrupt Processing Flow and Timing

3.3.4 Masking

Reset is non-maskable. All other interrupts can be enabled or disabled by the I mask bit in the CCR or by local mask bits in the peripheral control registers. The I bit may also be modified by execution of the set interrupt mask bit (SEI), clear interrupt mask bit (CLI), or transfer accumulator to condition code register (TAP) instructions. The I bit is modified in the first cycle of each instruction (these are all 2-cycle instructions). The I bit is also set during interrupt processing (see [3.3.1 Recognition](#)) and is cleared during the second cycle of the RTI instruction when the CCR is unstacked, provided that the stacked CCR I bit is not modified at the interrupt service routine. (See [3.3.5 Returning to Calling Program](#).)

In all cases where the I bit can be modified, it is modified at least one cycle prior to the last cycle of the instruction or operation, which guarantees that the new I-bit state will be effective prior to execution of the next instruction. For example, if an interrupt is recognized during the CLI instruction, the load accumulator from memory (LDA) instruction will not be executed before the interrupt is serviced. See [Figure 3-4](#).

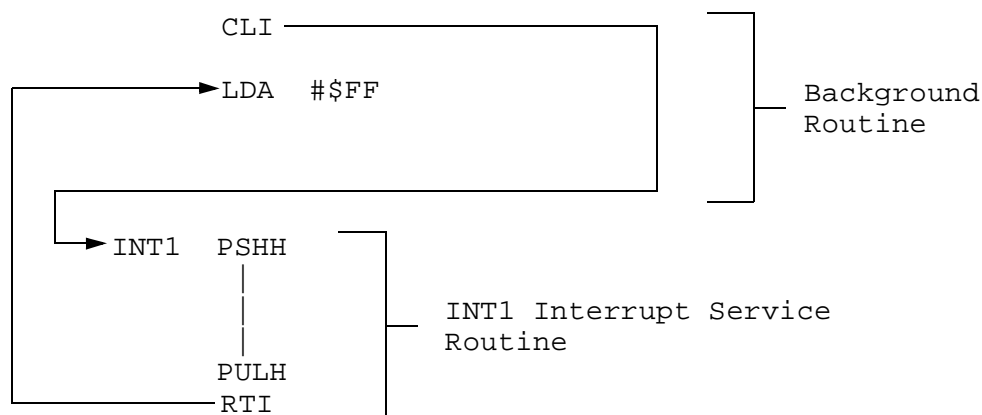

Figure 3-4. Interrupt Recognition Example 1

If an interrupt is pending upon exit from the original interrupt service routine, it will also be serviced before the LDA instruction is executed. Note that the LDA opcode is prefetched by both the INT1 and INT2 RTI instructions. However, in the case of the INT1 RTI prefetch, this is a redundant operation. See [Figure 3-5](#).

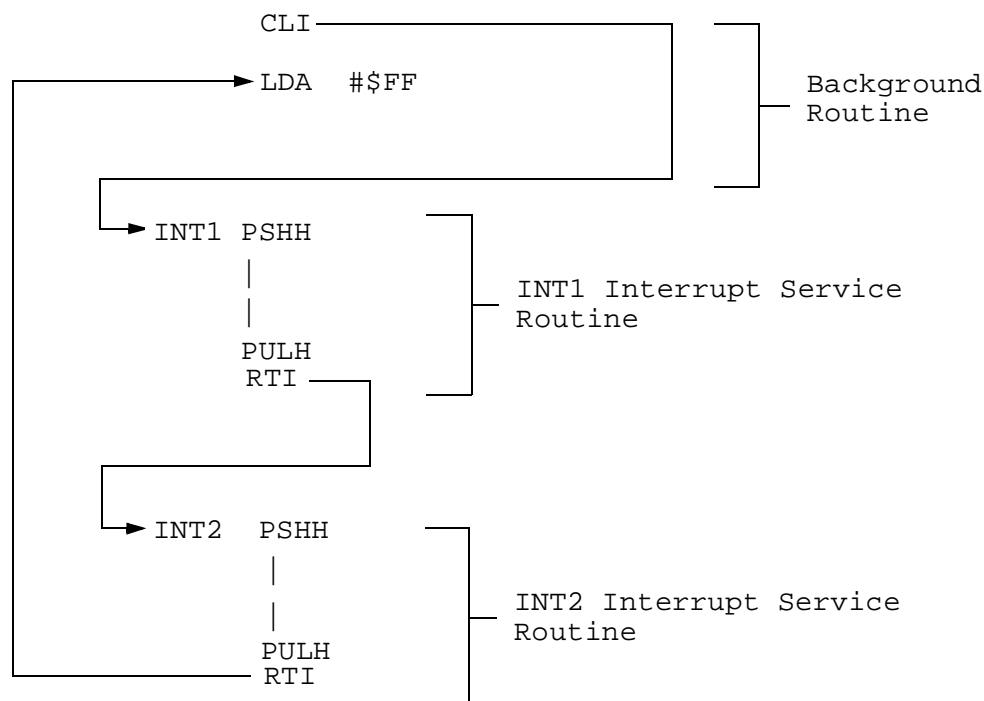

Figure 3-5. Interrupt Recognition Example 2

Similarly, in [Figure 3-6](#), if an interrupt is recognized during the **CLI** instruction, it will be serviced before the **SEI** instruction sets the **I** bit in the **CCR**.

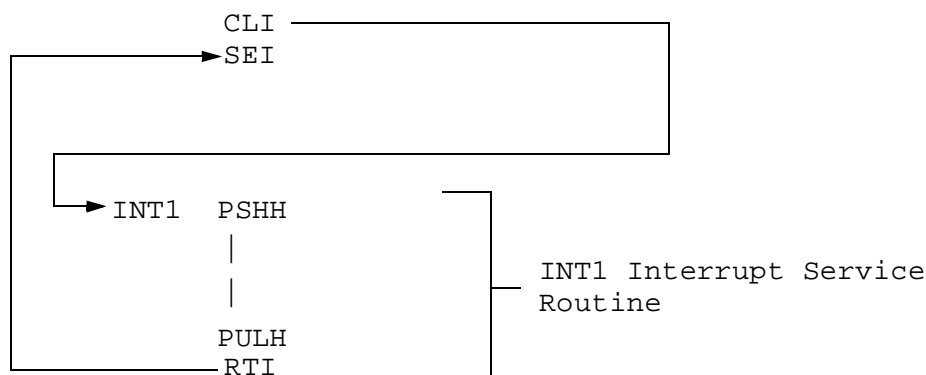

Figure 3-6. Interrupt Recognition Example 3

3.3.5 Returning to Calling Program

When an interrupt has been serviced, the RTI instruction terminates interrupt processing and returns to the program that was running at the time of the interrupt. In servicing the interrupt, some or all of the CPU08 registers will have changed. To continue the former program as though uninterrupted, the registers must be restored to the values present at the time the former program was interrupted. The RTI instruction takes care of this by pulling (loading) the saved register values from the stack memory. The last value to be pulled from the stack is the program counter, which causes processing to resume at the point where it was interrupted.

Unstacking the CCR generally clears the I bit, which is cleared during the second cycle of the RTI instruction.

NOTE: *Since the return I bit state comes from the stacked CCR, the user, by setting the I bit in the stacked CCR, can block all subsequent interrupts pending or otherwise, regardless of priority, from within an interrupt service routine.*

```
LDA      #$08
ORA      1, SP
STA      1, SP
RTI
```

This capability can be useful in handling a transient situation where the interrupt handler detects that the background program is temporarily unable to cope with the interrupt load and needs some time to recover. At an appropriate juncture, the background program would reinstate interrupts after it has recovered.

3.4 Reset Processing

Reset forces the microcontroller unit (MCU) to assume a set of initial conditions and to begin executing instructions from a predetermined starting address. For the M68HC08 Family, reset assertion is asynchronous with instruction execution, and so the initial conditions can be assumed to take effect almost immediately after applying an active low level to the reset pin, regardless of whether the clock has started. Internally, reset is a clocked process, and so reset negation is synchronous with an internal clock, as shown in [Figure 3-7](#), which shows the internal timing for exiting a pin reset.

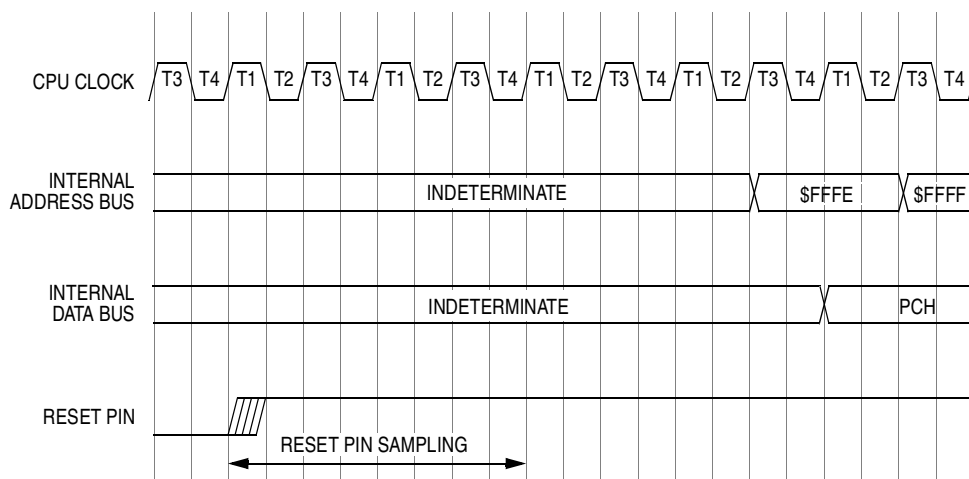

Figure 3-7. Exiting Reset

The reset system is able to actively pull down the reset output if reset-causing conditions are detected by internal systems. This feature can be used to reset external peripherals or other slave MCU devices.

3.4.1 Initial Conditions Established

Once the reset condition is recognized, internal registers and control bits are forced to an initial state. These initial states are described throughout this manual. These initial states in turn control on-chip peripheral systems to force them to known startup states. Most of the initial conditions are independent of the operating mode. This subsection summarizes the initial conditions of the CPU08 and input/output (I/O) as they leave reset.

3.4.2 CPU

After reset the CPU08 fetches the reset vector from locations \$FFFE and \$FFFF (when in monitor mode, the reset vector is fetched from \$FEFE and \$FEFF), loads the vector into the PC, and begins executing instructions. The stack pointer is loaded with \$00FF. The H register is cleared to provide compatibility for existing M6805 object code. All other CPU08 registers are indeterminate immediately after reset; however, the I interrupt mask bit in the condition code register is set to mask any interrupts, and the STOP and WAIT latches are both cleared.

3.4.3 Operating Mode Selection

The CPU08 has two modes of operation useful to the user:

- User mode
- Monitor mode

The monitor mode is the same as user mode except that alternate vectors are used by forcing address bit A8 to 0 instead of 1. The reset vector is therefore fetched from addresses \$FEFE and FEFF instead of FFFE and FFFF. This offset allows the CPU08 to execute code from the internal monitor firmware instead of the user code. (Refer to the appropriate technical data manual for specific information regarding the internal monitor description.)

The mode of operation is latched on the rising edge of the reset pin. The monitor mode is selected by connecting two port lines to V_{SS} and applying an over-voltage of approximately $2 \times V_{DD}$ to the $\overline{IRQ1}$ pin concurrent with the rising edge of reset (see [Table 3-1](#)). Port allocation varies from port to port.

Table 3-1. Mode Selection

$\overline{IRQ1}$ Pin	Port x	Port y	Mode
$\leq V_{DD}$	X	X	User
$2 \times V_{DD}$	1	0	Monitor

3.4.4 Reset Sources

The system integration module (SIM) has master reset control and may include, depending on device implementation, any of these typical reset sources:

- External reset (\overline{RESET} pin)
- Power-on reset (POR) circuit
- COP watchdog
- Illegal opcode reset
- Illegal address reset
- Low voltage inhibit (LVI) reset

A reset immediately stops execution of the current instruction. All resets produce the vector \$FFFE/\$FFFF and assert the internal reset signal. The internal reset causes all registers to return to their default values and all modules to return to their reset state.

3.4.5 External Reset

A logic 0 applied to the $\overline{\text{RESET}}$ pin asserts the internal reset signal, which halts all processing on the chip. The CPU08 and peripherals are reset.

3.4.6 Active Reset from an Internal Source

All internal reset sources actively pull down the $\overline{\text{RESET}}$ pin to allow the resetting of external peripherals. The $\overline{\text{RESET}}$ pin will be pulled down for 16 bus clock cycles; the internal reset signal will continue to be asserted for an additional 16 cycles after that. If the $\overline{\text{RESET}}$ pin is still low at the end of the second 16 cycles, then an external reset has occurred. If the pin is high, the appropriate bit will be set to indicate the source of the reset.

The active reset feature allows the part to issue a reset to peripherals and other chips within a system built around an M68HC08 MCU.

3.5 Interrupt Processing

The group of instructions executed in response to an interrupt is called an interrupt service routine. These routines are much like subroutines except that they are called through the automatic hardware interrupt mechanism rather than by a subroutine call instruction, and all CPU08 registers, except the H register, are saved on the stack. Refer to the description of the interrupt mask (I) found in [2.3.5 Condition Code Register](#).

An interrupt (provided it is enabled) causes normal program flow to be suspended as soon as the currently executing instruction finishes. The interrupt logic then pushes the contents of all CPU08 registers onto the stack, except the H register, so that the CPU08 contents can be restored after the interrupt is finished. After stacking the CPU08 registers, the vector for the highest priority pending interrupt source is loaded into the program counter and execution continues with the first instruction of the interrupt service routine.

An interrupt is concluded with a return-from-interrupt (RTI) instruction, which causes all CPU08 registers and the return address to be recovered from the stack, so that the interrupted program can resume as if there had been no interruption.

Interrupts can be enabled or disabled by the mask bit (I bit) in the condition code register and by local enable mask bits in the on-chip peripheral control registers. The interrupt mask bits in the CCR provide a means of controlling the nesting of interrupts.

In rare cases it may be useful to allow an interrupt routine to be interrupted (see [3.5.3 Nesting of Multiple Interrupts](#)). However, nesting is discouraged because it greatly complicates a system and rarely improves system performance.

By default, the interrupt structure inhibits interrupts during the interrupt entry sequence by setting the interrupt mask bit(s) in the CCR. As the CCR is recovered from the stack during the return from interrupt, the condition code bits return to the enabled state so that additional interrupts can be serviced.

Upon reset, the I bit is set to inhibit all interrupts. After minimum system initialization, software may clear the I bit by a TAP or CLI instruction, thus enabling interrupts.

3.5.1 Interrupt Sources and Priority

The CPU08 can have 128 separate vectors including reset and software interrupt (SWI), which leaves 126 inputs for independent interrupt sources. See [Table 3-2](#).

NOTE: *Not all CPU08 versions use all available interrupt vectors.*

Table 3-2. M68HC08 Vectors

Address	Reset	Priority
FFFE	Reset	1
FFFC	SWI	2
FFFA	IREQ[0]	3
:	:	:
FF02	IREQ[124]	127
FF00	IREQ[125]	128

When the system integration module (SIM) receives an interrupt request, processing begins at the next instruction boundary. The SIM performs the priority decoding necessary if more than one interrupt source is active at the same time. Also, the SIM encodes the highest priority interrupt request into a constant that the CPU08 uses to generate the corresponding interrupt vector.

NOTE: *The interrupt source priority for any specific module may not always be the same in different M68HC08 versions. For details about the priority assigned to interrupt sources in a specific M68HC08 device, refer to the SIM section of the technical data manual written for that device.*

As an instruction, SWI has the highest priority other than reset; once the SWI opcode is fetched, no other interrupt can be honored until the SWI vector has been fetched.

3.5.2 Interrupts in Stop and Wait Modes

In wait mode the CPU clocks are disabled, but other module clocks remain active. A module that is active during wait mode can wake the CPU08 by an interrupt if the interrupt is enabled. Processing of the interrupt begins immediately.

In stop mode, the system clocks do not run. The system control module inputs are conditioned so that they can be asynchronous. A particular module can wake the part from stop mode with an interrupt provided that the module has been designed to do so.

3.5.3 Nesting of Multiple Interrupts

Under normal circumstances, CPU08 interrupt processing arbitrates multiple pending interrupts, selects the highest, and leaves the rest pending. The I bit in the CCR is also set, preventing nesting of interrupts. While an interrupt is being serviced, it effectively becomes the highest priority task for the system. When servicing is complete, the assigned interrupt priority is re-established.

In certain systems where, for example, a low priority interrupt contains a long interrupt service routine, it may not be desirable to lock out all higher priority interrupts while the low priority interrupt executes. Although not generally advisable, controlled nesting of interrupts can be used to solve problems of this nature.

If nesting of interrupts is desired, the interrupt mask bit(s) must be cleared after entering the interrupt service routine. Care must be taken to specifically mask (disable) the present interrupt with a local enable mask bit or clear the interrupt source flag before clearing the mask bit in the CCR. Failure to do so will cause the same source to immediately interrupt, which will rapidly consume all available stack space.

3.5.4 Allocating Scratch Space on the Stack

In some systems, it is useful to allocate local variable or scratch space on the stack for use by the interrupt service routine. Temporary storage can also be obtained using the push (PSH) and pull (PUL) instructions; however, the last-in-first-out (LIFO) structure of the stack makes this impractical for more than one or two bytes. The CPU08 features the 16-bit add immediate value (signed) to stack pointer (AIS) instruction to allocate space. The stack pointer indexing instructions can then be used to access this data space, as demonstrated in this example.

```

IRQINT      PSHH                ;Save H register
            AIS      #-16       ;Allocate 16 bytes of local storage
            STA      3,SP       ;Store a value in the second byte
                                ;of local space

* Note:      The stack pointer must always point to the next
*            empty stack location.  The location addressed
*            by 0,SP should therefore never be used unless the
*            programmer can guarantee no subroutine calls from
*            within the interrupt service routine.
*
*            .
*            .
*            .
*            LDA      3,SP      ;Read the value at a later time
*            .
*            .
*            .
*            AIS      #16       ;Clean up stack
*            PULH                ;Restore H register
*            RTI                ;Return

* Note:      Subroutine calls alter the offset from the SP to
*            the local variable data space because of the
*            stacked return address.  If the user wishes to
*            access this data space from subroutines called
*            from within the interrupt service routine, then
*            the offsets should be adjusted by +2 bytes for each
*            level of subroutine nesting.

```

4.2 Introduction

This section describes the addressing modes of the M68HC08 central processor unit (CPU).

4.3 Addressing Modes

The CPU08 uses 16 addressing modes for flexibility in accessing data. These addressing modes define how the CPU finds the data required to execute an instruction.

The 16 addressing modes are:

- Inherent
- Immediate
- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset
- Stack pointer, 8-bit offset
- Stack pointer, 16-bit offset
- Relative
- Memory-to-memory (four modes):
 - Immediate to direct
 - Direct to direct
 - Indexed to direct with post increment
 - Direct to indexed with post increment
- Indexed with post increment
- Indexed, 8-bit offset with post increment

4.3.1 Inherent

Inherent instructions have no operand fetch associated with the instruction, such as decimal adjust accumulator (DAA), clear index high (CLRH), and divide (DIV). Some of the inherent instructions act on data in the CPU registers, such as clear accumulator (CLRA), and transfer condition code register to the accumulator (TPA). Inherent instructions require no memory address, and most are one byte long. **Table 4-1** lists the instructions that use inherent addressing.

The assembly language statements shown here are examples of the inherent addressing mode. In the code example and throughout this section, **bold** typeface instructions are examples of the specific addressing mode being discussed; a pound sign (#) before a number indicates an immediate operand. The default base is decimal. Hexadecimal numbers are represented by a dollar sign (\$) preceding the number. Some assemblers use hexadecimal as the default numbering system. Refer to the documentation for the particular assembler to determine the proper syntax.

Machine Code	Label	Operation	Operand	Comments
A657	EX_1	LDA	#\$57	;A = \$57
AB45		ADD	#\$45	;A = \$9C
72		DAA		;A = \$02 w/carry ;bit set = \$102
A614	EX_2	LDA	#20	;LS dividend in A
8C		CLRH		;Clear MS dividend
AE03		LDX	#3	;Divisor in X
52		DIV		;(H:A)/X→A=06,H=02
A630	EX_3	LDA	#\$30	;A = \$30
87		PSHA		;Push \$30 on stack and ;decrement stack ;pointer by 1

Table 4-1. Inherent Addressing Instructions

Instruction	Mnemonic
Arithmetic Shift Left	ASLA, ASLX
Arithmetic Shift Right	ASRA, ASRX
Clear Carry Bit	CLC
Clear Interrupt Mask	CLI
Clear	CLRA, CLRX
Clear H (Index Register High)	CLRH
Complement	COMA, COMX
Decimal Adjust Accumulator	DAA
Decrement Accumulator, Branch if Not Equal (\$00)	DBNZA
Decrement X (Index Register Low), Branch if Not Equal (\$00)	DBNZX
Decrement	DECA, DECX
Divide (Integer 16-Bit by 8-Bit Divide)	DIV
Increment	INCA, INCX
Logical Shift Left	LSLA, LSLX
Logical Shift Right	LSRA, LSRX
Multiply	MUL
Negate	NEGA, NEGX
Nibble Swap Accumulator	NSA
No Operation	NOP
Push Accumulator onto Stack	PSHA
Push H (Index Register High) onto Stack	PSHH
Push X (Index Register Low) onto Stack	PSHX
Pull Accumulator from Stack	PULA
Pull H (Index Register High) from Stack	PULH
Pull X (Index Register Low) from Stack	PULX
Rotate Left through Carry	ROLA, ROLX
Rotate Right through Carry	RORA, RORX
Reset Stack Pointer to \$00FF	RSP
Return from Interrupt	RTI
Return from Subroutine	RTS
Set Carry Bit	SEC
Set Interrupt Mask	SEI

Table 4-1. Inherent Addressing Instructions (Continued)

Instruction	Mnemonic
Enable $\overline{\text{IRQ}}$ and Stop Oscillator	STOP
Software Interrupt	SWI
Transfer Accumulator to Condition Code Register	TAP
Transfer Accumulator to X (Index Register Low)	TAX
Transfer Condition Code Register to Accumulator	TPA
Test for Negative or Zero	TSTA, TSTX
Transfer Stack Pointer to Index Register (H:X)	TSX
Transfer X (Index Register Low) to Accumulator	TXA
Transfer Index Register (H:X) to Stack Pointer	TXS
Enable Interrupts and Halt CPU	WAIT

4.3.2 Immediate

The operand in immediate instructions is contained in the bytes immediately following the opcode. The byte or bytes that follow the opcode are the value of the statement rather than the address of the value. In this case, the effective address of the instruction is specified by the # sign and implicitly points to the byte following the opcode. The immediate value is limited to either one or two bytes, depending on the size of the register involved in the instruction. [Table 4-2](#) lists the instructions that use immediate addressing.

Immediate instructions associated with the index register (H:X) are 3-byte instructions: one byte for the opcode, two bytes for the immediate data byte.

The example code shown here contains two immediate instructions: AIX (add immediate to H:X) and CPHX (compare H:X with immediate value). H:X is first cleared and then incremented by one until it contains \$FFFF. Once the condition specified by the CPHX becomes true, the program branches to START, and the process is repeated indefinitely.

Addressing Modes

Machine Code	Label	Operation	Operand	Comments
5F	START	CLR _X		;X = 0
8C		CLR _H		;H = 0
AF01	TAG	AIX	#1	;(H:X) = (H:X) + 1
65FFFF		CPHX	#\$FFFF	;Compare (H:X) to ;\$FFFF
26F9		BNE	TAG	;Loop until equal
20F5		BRA	START	;Start over

Table 4-2. Immediate Addressing Instructions

Instruction	Mnemonic
Add with Carry Immediate Value to Accumulator	ADC
Add Immediate Value to Accumulator	ADD
Add Immediate Value (Signed) to Stack Pointer	AIS
Add Immediate Value (Signed) to Index Register (H:X)	AIX
Logical AND Immediate Value with Accumulator	AND
Bit Test Immediate Value with Accumulator	BIT
Compare A with Immediate and Branch if Equal	CBEQA
Compare X (Index Register Low) with Immediate and Branch if Equal	CBEQX
Compare Accumulator with Immediate Value	CMP
Compare Index Register (H:X) with Immediate Value	CPHX
Compare X (Index Register Low) with Immediate Value	CPX
Exclusive OR Immediate Value with Accumulator	EOR
Load Accumulator from Immediate Value	LDA
Load Index Register (H:X) with Immediate Value	LDHX
Load X (Index Register Low) from Immediate Value	LDX
Inclusive OR Immediate Value	ORA
Subtract with Carry Immediate Value	SBC
Subtract Immediate Value	SUB

4.3.3 Direct

Most direct instructions can access any of the first 256 memory addresses with only two bytes. The first byte is the opcode, and the second is the low byte of the operand address. The high-order byte of the effective address is assumed to be \$00 and is not included as an instruction byte (saving program memory space and execution time). The use of direct addressing mode is therefore limited to operands in the \$0000–\$00FF area of memory (called the direct page or page 0).

Direct addressing instructions take one less byte of program memory space than the equivalent instructions using extended addressing. By eliminating the additional memory access, the execution time is reduced by one cycle. In the course of a long program, this savings can be substantial. Most microcontroller units place some if not all random-access memory (RAM) in the \$0000–\$00FF area; this allows the designer to assign these locations to frequently referenced data variables, thus saving execution time.

BRSET and BRCLR are 3-byte instructions that use direct addressing to access the operand and relative addressing to specify a branch destination.

CPHX, STHX, and LDHX are 2-byte instructions that fetch a 16-bit operand. The most significant byte comes from the direct address; the least significant byte comes from the direct address + 1.

Table 4-3 lists the instructions that use direct addressing.

This example code contains two direct addressing mode instructions: STHX (store H:X in memory) and CPHX (compare H:X with memory). The first STHX instruction initializes RAM storage location TEMP to zero, and the second STHX instruction loads TEMP with \$5555. The CPHX instruction compares the value in H:X with the value of RAM:(RAM + 1).

Addressing Modes

In this example, RAM:(RAM + 1) = TEMP = \$50:\$51 = \$5555.

Machine Code	Label	Operation	Operand	Comments
	RAM	EQU	\$50	;RAM equate
	ROM	EQU	\$6E00	;ROM equate
		ORG	\$RAM	;Beginning of RAM
	TEMP	RMB	2	;Reserve 2 bytes
		ORG	\$ROM	;Beginning of ROM
5F	START	CLRX		;X = 0
8C		CLRH		;H = 0
3550		STHX	TEMP	;H:X=0 > temp
455555		LDHX	#\$5555	;Load H:X with \$5555
3550		STHX	TEMP	;Temp=\$5555
7550	BAD_PART	CPHX	RAM	;RAM=temp
26FC		BNE	BAD_PART	;RAM=temp will be ;same unless something ;is very wrong!
20F1		BRA	START	;Do it again

Table 4-3. Direct Addressing Instructions

Instruction	Mnemonic
Add Memory and Carry to Accumulator	ADC
Add Memory and Accumulator	ADD
Logical AND of Memory and Accumulator	AND
Arithmetic Shift Left Memory	ASL ⁽¹⁾
Arithmetic Shift Right Memory	ASR
Clear Bit in Memory	BCLR
Bit Test Memory with Accumulator	BIT
Branch if Bit n in Memory Clear	BRCLR
Branch if Bit n in Memory Set	BRSET
Set Bit in Memory	BSET
Compare Direct with Accumulator and Branch if Equal	CBEQ
Clear Memory	CLR
Compare Accumulator with Memory	CMP
Complement Memory	COM
Compare Index Register (H:X) with Memory	CPHX

Table 4-3. Direct Addressing Instructions (Continued)

Instruction	Mnemonic

4.3.4 Extended

Extended instructions can access any address in a 64-Kbyte memory map. All extended instructions are three bytes long. The first byte is the opcode; the second and third bytes are the most significant and least significant bytes of the operand address. This addressing mode is selected when memory above the direct or zero page (\$0000–\$00FF) is accessed.

Addressing Modes

When using most assemblers, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction. Table 4-4 lists the instructions that use the extended addressing mode. An example of the extended addressing mode is shown here.

Machine Code	Label	Operation	Operand	Comments
5F BE50		ORG	\$50	;Start at \$50
		FCB	\$FF	;\$50 = \$FF
		CLR X		
		LDX	\$0050	;Load X direct
5F CE6E00		ORG	\$6E00	;Start at \$6E00
		FCB	\$FF	;\$6E00 = \$FF
		CLR X		
		LDX	\$6E00	;Load X extended

Subtract Memory from Accumulator	SUB

4.3.5 Indexed, No Offset

Indexed instructions with no offset are 1-byte instructions that access data with variable addresses. X contains the low byte of the conditional address of the operand; H contains the high byte. Due to the addition of the H register, this addressing mode is not limited to the first 256 bytes of memory as in the M68HC05.

If none of the M68HC08 instructions that modify H are used (AIX; CBEQ (ix+); LDHX; MOV (dir/ix+); MOV (ix+/dir); DIV; PULH; TSX), then the H value will be \$00, which ensures complete source code compatibility with M68HC05 Family instructions.

Indexed, no offset instructions can move a pointer through a table or hold the address of a frequently used RAM or input/output (I/O) location.

Table 4-5 lists instructions that use indexed, no offset addressing.

4.3.6 Indexed, 8-Bit Offset

Indexed, 8-bit offset instructions are 2-byte instructions that can access data with variable addresses. The CPU adds the unsigned bytes in H:X to the unsigned byte following the opcode. The sum is the effective address of the operand.

If none of the M68HC08 instructions that modify H are used (AIX; CBEQ (ix+); LDHX; MOV (dir/ix+); MOV (ix+/dir); DIV; PULH; TSX), then the H value will be \$00, which ensures complete source code compatibility with the M68HC05 Family instructions.

Indexed, 8-bit offset instructions are useful in selecting the kth element in an n-element table. The table can begin anywhere and can extend as far as the address map allows. The k value would typically be in H:X, and the address of the beginning of the table would be in the byte following the opcode. Using H:X in this way, this addressing mode is limited to the first 256 addresses in memory. Tables can be located anywhere in the address map when H:X is used as the base address, and the byte following is the offset.

Table 4-5 lists the instructions that use indexed, 8-bit offset addressing.

4.3.7 Indexed, 16-Bit Offset

Indexed, 16-bit offset instructions are 3-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned contents of H:X to the 16-bit unsigned word formed by the two bytes following the opcode. The sum is the effective address of the operand. The first byte after the opcode is the most significant byte of the 16-bit offset; the second byte is the least significant byte of the offset.

As with direct and extended addressing, most assemblers determine the shortest form of indexed addressing. [Table 4-5](#) lists the instructions that use indexed, 16-bit offset addressing.

Indexed, 16-bit offset instructions are useful in selecting the kth element in an n-element table. The table can begin anywhere and can extend as far as the address map allows. The k value would typically be in H:X, and the address of the beginning of the table would be in the bytes following the opcode.

This example uses the JMP (unconditional jump) instruction to show the three different types of indexed addressing.

Machine Code	Label	Operation	Operand	Comments
FC		JMP	,X	;No offset ;Jump to address ;pointed to by H:X
ECFF		JMP	\$FF,X	;8-bit offset ;Jump to address ;pointed to by H:X + \$FF
DC10FF		JMP	\$10FF,X	;16-bit offset ;Jump to address ;pointed to by H:X + \$10FF

4.3.8 Stack Pointer, 8-Bit Offset

Stack pointer, 8-bit offset instructions are 3-byte instructions that address operands in much the same way as indexed 8-bit offset instructions, only they add the 8-bit offset to the value of the stack pointer instead of the index register.

The stack pointer, 8-bit offset addressing mode permits easy access of data on the stack. The CPU adds the unsigned byte in the 16-bit stack pointer (SP) register to the unsigned byte following the opcode. The sum is the effective address of the operand.

If interrupts are disabled, this addressing mode allows the stack pointer to be used as a second “index” register. [Table 4-6](#) lists the instructions that can be used in the stack pointer, 8-bit offset addressing mode.

Stack pointer relative instructions require a pre-byte for access. Consequently, all SP relative instructions take one cycle longer than their index relative counterparts.

4.3.9 Stack Pointer, 16-Bit Offset

Stack pointer, 16-bit offset instructions are 4-byte instructions used to access data relative to the stack pointer with variable addresses at any location in memory. The CPU adds the unsigned contents of the 16-bit stack pointer register to the 16-bit unsigned word formed by the two bytes following the opcode. The sum is the effective address of the operand.

As with direct and extended addressing, most assemblers determine the shortest form of stack pointer addressing. Due to the pre-byte, stack pointer relative instructions take one cycle longer than their index relative counterparts. [Table 4-6](#) lists the instructions that can be used in the stack pointer, 16-bit offset addressing mode.

Examples of the 8-bit and 16-bit offset stack pointer addressing modes are shown here. The first example stores the value of \$20 in location \$10, $SP = \$10 + \$FF = \$10F$ and then decrements that location until equal to zero. The second example loads the accumulator with the contents of memory location \$250, $SP = \$250 + \$FF = \$34F$.

Machine Code	Label	Operation	Operand	Comments
450100		LDHX	#\$0100	
94		TXS		;Reset stack pointer ;to \$00FF

94		TXS		;Reset stack pointer ;to \$00FF
9ED60250		LDA	\$0250,SP	;16-bit offset ;Load A with contents ;of \$34F

Stack pointer, 16-bit offset instructions are useful in selecting the kth element in an n-element table. The table can begin anywhere and can extend anywhere in memory. With this 4-byte instruction, the k value would typically be in the stack pointer register, and the address of the beginning of the table is located in the two bytes following the 2-byte opcode.

1. ASL = LSL

4.3.10 Relative

All conditional branch instructions use relative addressing to evaluate the resultant effective address (EA). The CPU evaluates the conditional branch destination by adding the signed byte following the opcode to the contents of the program counter. If the branch condition is true, the PC is loaded with the EA. If the branch condition is not true, the CPU goes to the next instruction. The offset is a signed, two's complement byte that gives a branching range of -128 to $+127$ bytes from the address of the next location after the branch instruction.

Four new branch opcodes test the N, Z, and V (overflow) bits to determine the relative signed values of the operands. These new opcodes are BLT, BGT, BLE, and BGE and are designed to be used with signed arithmetic operations.

When using most assemblers, the programmer does not need to calculate the offset, because the assembler determines the proper offset and verifies that it is within the span of the branch.

Table 4-7 lists the instructions that use relative addressing.

This example contains two relative addressing mode instructions: BLT (branch if less than, signed operation) and BRA (branch always). In this example, the value in the accumulator is compared to the signed value -2 . Because $\#1$ is greater than -2 , the branch to TAG will not occur.

Machine Code	Label	Operation	Operand	Comments
A601	TAG	LDA	#1	;A = 1
A1FE		CMP	#-2	;Compare with -2
91FA		BLT	TAG	;Branch if value of A ;is less than -2
20FE	HERE	BRA	HERE	;Branch always

4.3.11 Memory-to-Memory Immediate to Direct

Move immediate to direct (MOV imm/dir) is a 3-byte, 4-cycle addressing mode generally used to initialize variables and registers in the direct page. The operand in the byte immediately following the opcode is stored in the direct page location addressed by the second byte following the opcode. The MOV instruction associated with this addressing mode does not affect the accumulator value. This example shows that by eliminating the accumulator from the data transfer process, the number of execution cycles decreases from 9 to 4 for a similar immediate to direct operation.

	Machine Code	Label	Operation	Operand	Comments
* Data movement with accumulator					
B750	(2 cycles)		PSHA		;Save current A ; value
A622	(2 cycles)		LDA	#\$22	;A = \$22
B7F0	(3 cycles)		STA	\$F0	;Store \$22 into \$F0
B650	(2 cycles)		PULA		;Restore A value
	9 cycles				
* Data movement without accumulator					
6E22F0	(4 cycles)		MOV	#\$22,\$F0	;Location \$F0 ;= \$22

4.3.12 Memory-to-Memory Direct to Direct

Move direct to direct (MOV dir/dir) is a 3-byte, 5-cycle addressing mode generally used in register-to-register movements of data from within the direct page. The operand in the direct page location addressed by the byte immediately following the opcode is stored in the direct page location addressed by the second byte following the opcode. The MOV instruction associated with this addressing mode does not affect the accumulator value. As with the previous addressing mode,

Addressing Modes

eliminating the accumulator from the data transfer process reduces the number of execution cycles from 10 to 5 for similar direct-to-direct operations (see example). This savings can be substantial for a program containing numerous register-to-register data transfers.

Machine Code		Label	Operation	Operand	Comments
* Data movement with accumulator					
B750	(2 cycles)		PSHA		;Save A value
B6F0	(3 cycles)		LDA	\$F0	;Get contents ;of \$F0
B7F1	(3 cycles)		STA	\$F1	;Location \$F1=\$F0
B650	(2 cycles)		PULA		;Restore A value
	10 cycles				
* Data movement without accumulator					
4EF0F1	(5 cycles)		MOV	\$F0,\$F1	;Move contents of ;\$F0 to \$F1

4.3.13 Memory-to-Memory Indexed to Direct with Post Increment

Move indexed to direct, post increment (MOV ix+/dir) is a 2-byte, 4-cycle addressing mode generally used to transfer tables addressed by the index register to a register in the direct page. The tables can be located anywhere in the 64-Kbyte map and can be any size. This instruction does not affect the accumulator value. The operand addressed by H:X is stored in the direct page location addressed by the byte following the opcode. H:X is incremented after the move.

This addressing mode is effective for transferring a buffer stored in RAM to a serial transmit register, as shown in the following example. [Table 4-8](#) lists the memory-to-memory move instructions.

NOTE: *Move indexed to direct, post increment instructions will increment H if X is incremented past \$FF.*

This example illustrates an interrupt-driven SCI transmit service routine supporting a circular buffer.

Machine Code	Label	Operation	Operand	Comments
	SIZE	EQU	16	;TX circular ;buffer length

80		RTI		;Return

4.3.14 Memory-to-Memory Direct to Indexed with Post Increment

Move direct to indexed, post increment (MOV dir/ix+) is a 2-byte, 4-cycle addressing mode generally used to fill tables from registers in the direct page. The tables can be located anywhere in the 64-Kbyte map and can be any size. The instruction associated with this addressing mode does not affect the accumulator value. The operand in the direct page location addressed by the byte immediately following the opcode is stored in the location addressed by H:X. H:X is incremented after the move.

An example of this addressing mode would be in filling a serial receive buffer located in RAM from the receive data register. [Table 4-8](#) lists the memory-to-memory move instructions.

NOTE: *Move direct to indexed, post increment instructions will increment H if X is incremented past \$FF.*

This example illustrates an interrupt-driven SCI receive service routine supporting a circular buffer.

Machine Code	Label	Operation	Operand	Comments
	SIZE	EQU	16	;RX circular ;buffer length

Move Direct Memory Operand to Indexed Memory Location	MOV

4.3.15 Indexed with Post Increment

Indexed, no offset with post increment instructions are 2-byte instructions that address operands, then increment H:X. X contains the low byte of the conditional address of the operand; H contains the high byte. The sum is the conditional address of the operand. This addressing mode is generally used for table searches. [Table 4-9](#) lists the indexed with post increment instructions.

NOTE: *Indexed with post increment instructions will increment H if X is incremented past \$FF.*

Addressing Modes

4.3.16 Indexed, 8-Bit Offset with Post Increment

Indexed, 8-bit offset with post increment instructions are 3-byte instructions that access operands with variable addresses, then increment H:X. X contains the low byte of the conditional address of the operand; H contains the high byte. The sum is the conditional address of the operand. As with indexed, no offset, this addressing mode is generally used for table searches. [Table 4-9](#) lists the indexed with post increment instructions.

NOTE: *Indexed, 8-bit offset with post increment instructions will increment H if X is incremented past \$FF.*

This example uses the CBEQ (compare and branch if equal) instruction to show the two different indexed with post increment addressing modes.

BSR	Branch to Subroutine	132
CBEQ	Compare and Branch if Equal	133
CLC	Clear Carry Bit	134
CLI	Clear Interrupt Mask Bit	135
CLR	Clear	136
CMP	Compare Accumulator with Memory	137
COM	Complement (One's Complement)	138
CPHX	Compare Index Register with Memory	139
CPX	Compare X (Index Register Low) with Memory	140
DAA	Decimal Adjust Accumulator	141
DAA	Decimal Adjust Accumulator (Continued)	142
DBNZ	Decrement and Branch if Not Zero	143
DEC	Decrement	144
DIV	Divide	145
EOR	Exclusive-OR Memory with Accumulator	146
INC	Increment	147
JMP	Jump	148
JSR	Jump to Subroutine	149
LDA	Load Accumulator from Memory	150
LDHX	Load Index Register from Memory	151
LDX	Load X (Index Register Low) from Memory	152
LSL	Logical Shift Left	153
LSR	Logical Shift Right	154
MOV	Move	155

MUL	Unsigned Multiply	156
NEG	Negate (Two's Complement).	157
NOP	No Operation	158
NSA	Nibble Swap Accumulator	159
ORA	Inclusive-OR Accumulator and Memory	160
PSHA	Push Accumulator onto Stack	161
PSHH	Push H (Index Register High) onto Stack	162
PSHX	Push X (Index Register Low) onto Stack	163
PULA	Pull Accumulator from Stack	164
PULH	Pull H (Index Register High) from Stack	165
PULX	Pull X (Index Register Low) from Stack.	166
ROL	Rotate Left through Carry	167
ROR	Rotate Right through Carry	168
RSP	Reset Stack Pointer.	169
RTI	Return from Interrupt.	170
RTS	Return from Subroutine.	171
SBC	Subtract with Carry	172
SEC	Set Carry Bit	173
SEI	Set Interrupt Mask Bit	174
STA	Store Accumulator in Memory.	175
STHX	Store Index Register	176
STOP	Enable $\overline{\text{IRQ}}$ Pin, Stop Oscillator	177
STX	Store X (Index Register Low) in Memory	178
SUB	Subtract.	179
SWI	Software Interrupt	180
TAP	Transfer Accumulator to Processor Status Byte	181
TAX	Transfer Accumulator to X (Index Register Low)	182
TPA	Transfer Processor Status Byte to Accumulator	183
TST	Test for Negative or Zero	184
TSX	Transfer Stack Pointer to Index Register	185
TXA	Transfer X (Index Register Low) to Accumulator	186
TXS	Transfer Index Register to Stack Pointer	187
WAIT	Enable Interrupts; Stop Processor	188

5.2 Introduction

This section contains detailed information for all HC08 Family instructions. The instructions are arranged in alphabetical order with the instruction mnemonic set in larger type for easy reference.

5.3 Nomenclature

This nomenclature is used in the instruction descriptions throughout this section.

Operators

()	=	Contents of register or memory location shown inside parentheses
←	=	Is loaded with (read: “gets”)
&	=	Boolean AND
	=	Boolean OR
⊕	=	Boolean exclusive-OR
×	=	Multiply
÷	=	Divide
:	=	Concatenate
+	=	Add
−	=	Negate (two's complement)
«	=	Sign extend

CPU registers

A	=	Accumulator
CCR	=	Condition code register
H	=	Index register, higher order (most significant) eight bits
X	=	Index register, lower order (least significant) eight bits
PC	=	Program counter
PCH	=	Program counter, higher order (most significant) eight bits
PCL	=	Program counter, lower order (least significant) eight bits
SP	=	Stack pointer

Memory and addressing

- M = A memory location or absolute data, depending on addressing mode
- $M:M + \$0001$ = A 16-bit value in two consecutive memory locations. The higher-order (most significant) eight bits are located at the address of M , and the lower-order (least significant) eight bits are located at the next higher sequential address.
- rel = The relative offset, which is the two's complement number stored in the last byte of machine code corresponding to a branch instruction

Condition code register (CCR) bits

- V = Two's complement overflow indicator, bit 7
- H = Half carry, bit 4
- I = Interrupt mask, bit 3
- N = Negative indicator, bit 2
- Z = Zero indicator, bit 1
- C = Carry/borrow, bit 0 (carry out of bit 7)

Bit status BEFORE execution of an instruction ($n = 7, 6, 5, \dots 0$)

For 2-byte operations such as LDHX, STHX, and CPHX, $n = 15$ refers to bit 15 of the 2-byte word or bit 7 of the most significant (first) byte.

- Mn = Bit n of memory location used in operation
- An = Bit n of accumulator
- Hn = Bit n of index register H
- Xn = Bit n of index register X
- bn = Bit n of the source operand (M , A , or X)

Bit status AFTER execution of an instruction

For 2-byte operations such as LDHX, STHX, and CPHX, $n = 15$ refers to bit 15 of the 2-byte word or bit 7 of the most significant (first) byte.

- Rn = Bit n of the result of an operation ($n = 7, 6, 5, \dots 0$)

CCR activity figure notation

–	=	Bit not affected
0	=	Bit forced to 0
1	=	Bit forced to 1
↕	=	Bit set or cleared according to results of operation
U	=	Undefined after the operation

Machine coding notation

dd	=	Low-order eight bits of a direct address \$0000–\$00FF (high byte assumed to be \$00)
ee	=	Upper eight bits of 16-bit offset
ff	=	Lower eight bits of 16-bit offset or 8-bit offset
ii	=	One byte of immediate data
jj	=	High-order byte of a 16-bit immediate data value
kk	=	Low-order byte of a 16-bit immediate data value
hh	=	High-order byte of 16-bit extended address
ll	=	Low-order byte of 16-bit extended address
rr	=	Relative offset

Source forms

The instruction detail pages provide only essential information about assembler source forms. Assemblers generally support a number of assembler directives, allow definition of program labels, and have special conventions for comments. For complete information about writing source files for a particular assembler, refer to the documentation provided by the assembler vendor.

Typically, assemblers are flexible about the use of spaces and tabs. Often, any number of spaces or tabs can be used where a single space is shown on the glossary pages. Spaces and tabs are also normally allowed before and after commas. When program labels are used, there must also be at least one tab or space before all instruction mnemonics. This required space is not apparent in the source forms.

Everything in the source forms columns, *except expressions in italic characters*, is literal information which must appear in the assembly source file exactly as shown. The initial 3- to 5-letter mnemonic is always

a literal expression. All commas, pound signs (#), parentheses, and plus signs (+) are literal characters.

The definition of a legal label or expression varies from assembler to assembler. Assemblers also vary in the way CPU registers are specified. Refer to assembler documentation for detailed information.

Recommended register designators are a, A, h, H, x, X, sp, and SP.

- n* — Any label or expression that evaluates to a single integer in the range 0–7
- opr8i* — Any label or expression that evaluates to an 8-bit immediate value
- opr16i* — Any label or expression that evaluates to a 16-bit immediate value
- opr8a* — Any label or expression that evaluates to an 8-bit value. The instruction treats this 8-bit value as the low order eight bits of an address in the direct page of the 64-Kbyte address space (\$00xx).
- opr16a* — Any label or expression that evaluates to a 16-bit value. The instruction treats this value as an address in the 64-Kbyte address space.
- opr8* — Any label or expression that evaluates to an unsigned 8-bit value; used for indexed addressing
- opr16* — Any label or expression that evaluates to a 16-bit value. Since the MC68HC08S has a 16-bit address bus, this can be either a signed or an unsigned value.
- rel* — Any label or expression that refers to an address that is within –128 to +127 locations from the next address after the last byte of object code for the current instruction. The assembler will calculate the 8-bit signed offset and include it in the object code for this instruction.

Address modes

INH	=	Inherent (no operands)
IMM	=	8-bit or 16-bit immediate
DIR	=	8-bit direct
EXT	=	16-bit extended
IX	=	16-bit indexed no offset
IX+	=	16-bit indexed no offset, post increment (CBEQ and MOV only)
IX1	=	16-bit indexed with 8-bit offset from H:X
IX1+	=	16-bit indexed with 8-bit offset, post increment (CBEQ only)
IX2	=	16-bit indexed with 16-bit offset from H:X
REL	=	8-bit relative offset
SP1	=	Stack pointer relative with 8-bit offset
SP2	=	Stack pointer relative with 16-bit offset

5.4 Convention Definitions

Set refers specifically to establishing logic level 1 on a bit or bits.

Cleared refers specifically to establishing logic level 0 on a bit or bits.

A specific bit is referred to by mnemonic and bit number. A7 is bit 7 of accumulator A. **A range of bits** is referred to by mnemonic and the bit numbers that define the range. A [7:4] are bits 7 to 4 of the accumulator.

Parentheses indicate the contents of a register or memory location, rather than the register or memory location itself. (A) is the contents of the accumulator. In Boolean expressions, parentheses have the traditional mathematical meaning.

5.5 Instruction Set

The following pages summarize each instruction, including operation and description, condition codes and Boolean formulae, and a table with source forms, addressing modes, machine code, and cycles.

ADC

Add with Carry

ADC

Operation

$$A \leftarrow (A) + (M) + (C)$$

Description

Adds the contents of the C bit to the sum of the contents of A and M and places the result in A. This operation is useful for addition of operands that are larger than eight bits.

Condition Codes
and Boolean
Formulae

V			H	I	N	Z	C
↑	1	1	↑	—	↑	↑	↑

$$V: A7 \& M7 \& \overline{R7} \mid \overline{A7} \& \overline{M7} \& R7$$

Set if a two's complement overflow resulted from the operation; cleared otherwise

$$H: A3 \& M3 \mid M3 \& \overline{R3} \mid \overline{R3} \& A3$$

Set if there was a carry from bit 3; cleared otherwise

$$N: R7$$

Set if MSB of result is 1; cleared otherwise

$$Z: \overline{R7} \& \overline{R6} \& \overline{R5} \& \overline{R4} \& \overline{R3} \& \overline{R2} \& \overline{R1} \& \overline{R0}$$

Set if result is \$00; cleared otherwise

$$C: A7 \& M7 \mid M7 \& \overline{R7} \mid \overline{R7} \& A7$$

Set if there was a carry from the most significant bit (MSB) of the result; cleared otherwise

AIS

Add Immediate Value (Signed) to Stack Pointer

AIS

Operation
$$SP \leftarrow (SP) + (16 \ll M)$$
Description

Adds the immediate operand to the stack pointer (SP). The immediate value is an 8-bit two's complement signed operand. The 8-bit operand is sign-extended to 16 bits prior to the addition. The AIS instruction can be used to create and remove a stack frame buffer that is used to store temporary variables.

This instruction does not affect any condition code bits so status information can be passed to or from a subroutine or C function and allocation or deallocation of space for local variables will not disturb that status information.

Condition Codes and Boolean Formulae

Instruction Set

AIX**Add Immediate Value (Signed) to Index Register****AIX****Operation**

$$H:X \leftarrow (H:X) + (16 \ll M)$$
Description

Adds an immediate operand to the 16-bit index register, formed by the concatenation of the H and X registers. The immediate operand is an 8-bit two's complement signed offset. The 8-bit operand is sign-extended to 16 bits prior to the addition.

This instruction does not affect any condition code bits so index register pointer calculations do not disturb the surrounding code which may rely on the state of CCR status bits.

Condition Codes and Boolean Formulae

AND

Logical AND

AND

Operation

 $A \leftarrow (A) \& (M)$

Description

Performs the logical AND between the contents of A and the contents of M and places the result in A. Each bit of A after the operation will be the logical AND of the corresponding bits of M and of A before the operation.

ASL

Arithmetic Shift Left
(Same as LSL)

ASL

Operation

Description

Shifts all bits of A, X, or M one place to the left. Bit 0 is loaded with a 0. The C bit in the CCR is loaded from the most significant bit of A, X, or M. This is mathematically equivalent to multiplication by two. The V bit indicates whether the sign of the result has changed.

Condition Codes
and Boolean
Formulae

ASR

Arithmetic Shift Right

ASR

Operation

Description

Shifts all bits of A, X, or M one place to the right. Bit 7 is held constant. Bit 0 is loaded into the C bit of the CCR. This operation effectively divides a two's complement value by 2 without changing its sign. The carry bit can be used to round the result.

Condition Codes and Boolean Formulae

V			H	I	N	Z	C
↓	1	1	—	—	↓	↓	↓

V: $R7 \oplus b0$

Set if the exclusive-OR of the resulting N and C flags is 1; cleared otherwise

N: R7

Set if MSB of result is 1; cleared otherwise

Z: $\overline{R7} \& \overline{R6} \& \overline{R5} \& \overline{R4} \& \overline{R3} \& \overline{R2} \& \overline{R1} \& \overline{R0}$

Set if result is \$00; cleared otherwise

C: b0

Set if, before the shift, the LSB of A, X, or M was set; cleared otherwise

BCLR n **Clear Bit n in Memory****BCLR n** **Operation** $Mn \leftarrow 0$ **Description**

Clear bit n ($n = 7, 6, 5, \dots 0$) in location M. All other bits in M are unaffected. In other words, M can be any random-access memory (RAM) or input/output (I/O) register address in the \$0000 to \$00FF area of memory. (Direct addressing mode is used to specify the address of the operand.) This instruction reads the specified 8-bit location, modifies the specified bit, and then writes the modified 8-bit value back to the memory location.

BEQ**Branch if Equal****BEQ****Operation**

If $(Z) = 1$, $PC \leftarrow (PC) + \$0002 + rel$

Simple branch; may be used with signed or unsigned operations

Description

Tests the state of the Z bit in the CCR and causes a branch if Z is set. Compare instructions perform a subtraction with two operands and produce an internal result without changing the original operands. If the two operands were equal, the internal result of the subtraction for the compare will be zero so the Z bit will be equal to one and the BEQ will cause a branch.

This instruction can also be used after a load or store without having to do a separate test or compare on the loaded value. See the [BRA](#) instruction for further details of the execution of the branch.

BHCC

Branch if Half Carry Bit Clear

BHCC

Operation

If (H) = 0, $PC \leftarrow (PC) + \$0002 + rel$

Description

Tests the state of the H bit in the CCR and causes a branch if H is clear. This instruction is used in algorithms involving BCD numbers that were originally written for the M68HC05 or M68HC08 devices. The DAA instruction in the HC08 simplifies operations on BCD numbers so BHCC and BHCS should not be needed in new programs. See the [BRA](#) instruction for further details of the execution of the branch.

Instruction Set

BHI

Branch if Higher

BHI

Operation

If $(C) \mid (Z) = 0$, $PC \leftarrow (PC) + \$0002 + rel$

For unsigned values, if (Accumulator) > (Memory), then branch

Description

Causes a branch if both C and Z are cleared. If the BHI instruction is executed immediately after execution of a CMP, CPHX, CPX, SBC, or SUB instruction, the branch will occur if the unsigned binary number in the A, X, or H:X register was greater than unsigned binary number in memory. Generally not useful after CLR, COM, DEC, INC, LDA, LDHX, LDX, STA, STHX, STX, or TST because these instructions do not affect the carry bit in the CCR. See the [BRA](#) instruction for details of the execution of the branch.

BIT

Bit Test

BIT

Operation

(A) & (M)

Description

Performs the logical AND comparison of the contents of A and the contents of M and modifies the condition codes accordingly. Neither the contents of A nor M are altered. (Each bit of the result of the AND would be the logical AND of the corresponding bits of A and M.)

This instruction is typically used to see if a particular bit, or any of several bits, in a byte are 1s. A mask value is prepared with 1s in any bit positions that are to be checked. This mask may be in accumulator A or memory and the unknown value to be checked will be in memory or the accumulator A, respectively. After the BIT instruction, a BNE instruction will branch if any bits in the tested location that correspond to 1s in the mask were 1s.

BMI**Branch if Minus****BMI****Operation**

If (N) = 1, $PC \leftarrow (PC) + \$0002 + rel$

Simple branch; may be used with signed or unsigned operations

Description

Tests the state of the N bit in the CCR and causes a branch if N is set.

Simply loading or storing A, X, or H:X will cause the N condition code bit to be set or cleared to match the most significant bit of the value loaded or stored. The BMI instruction can be used after such a load or store without having to do a separate test or compare instruction before the conditional branch. See the [BRA](#) instruction for further details of the execution of the branch.

Instruction Set

BNE

Branch if Not Equal

BNE

Operation

If $(Z) = 0$, $PC \leftarrow (PC) + \$0002 + rel$

Simple branch, may be used with signed or unsigned operations

Description

Tests the state of the Z bit in the CCR and causes a branch if Z is clear

Following a compare or subtract instruction, the branch will occur if the arguments were not equal. This instruction can also be used after a load or store without having to do a separate test or compare on the loaded value. See the **BRA** instruction for further details of the execution of the branch.

BRA**Branch Always****BRA****Operation**

$$PC \leftarrow (PC) + \$0002 + rel$$
Description

Performs an unconditional branch to the address given in the foregoing formula. In this formula, *rel* is the two's-complement relative offset in the last byte of machine code for the instruction and (PC) is the address of the opcode for the branch instruction.

A source program specifies the destination of a branch instruction by its absolute address, either as a numerical value or as a symbol or expression which can be numerically evaluated by the assembler. The assembler calculates the 8-bit relative offset *rel* from this absolute address and the current value of the location counter.

$\overline{\text{IRQ}}$ high	—	BIH	2F	—	BIL	2E	Simple
Always	—	BRA	20	Never	BRN	21	Uncond.

r = register: A, X, or H:X (for CPHX instruction) m = memory operand

During program execution, if the tested condition is true, the two's complement offset is sign-extended to a 16-bit value which is added to the current program counter. This causes program execution to continue at the address specified as the branch destination. If the tested condition is not true, the program simply continues to the next instruction after the branch.

Instruction Set

BRCLR *n*Branch if Bit *n* in Memory Clear**BRCLR *n*****Operation**If bit *n* of M = 0, PC ← (PC) + \$0003 + *rel***Description**

Tests bit *n* (*n* = 7, 6, 5, ... 0) of location M and branches if the bit is clear. M can be any RAM or I/O register address in the \$0000 to \$00FF area of memory because direct addressing mode is used to specify the address of the operand.

The C bit is set to the state of the tested bit. When used with an appropriate rotate instruction, BRCLR *n* provides an easy method for performing serial-to-parallel conversions.

BRN**Branch Never****BRN****Operation** $PC \leftarrow (PC) + \$0002$ **Description**

Never branches. In effect, this instruction can be considered a 2-byte no operation (NOP) requiring three cycles for execution. Its inclusion in the instruction set provides a complement for the **BRA** instruction. The BRN instruction is useful during program debugging to negate the effect of another branch instruction without disturbing the offset byte.

This instruction can be useful in instruction-based timing delays. Instruction-based timing delays are usually discouraged because such code is not portable to systems with different clock speeds.

BSET n **Set Bit n in Memory****BSET n** **Operation** $Mn \leftarrow 1$ **Description**

Set bit n ($n = 7, 6, 5, \dots 0$) in location M. All other bits in M are unaffected. M can be any RAM or I/O register address in the \$0000 to \$00FF area of memory because direct addressing mode is used to specify the address of the operand. This instruction reads the specified 8-bit location, modifies the specified bit, and then writes the modified 8-bit value back to the memory location.

BSR

Branch to Subroutine

BSR

Operation

 $PC \leftarrow (PC) + \$0002$

Advance PC to return address

 $Push(PCL); SP \leftarrow (SP) - \0001

Push low half of return address

 $Push(PCH); SP \leftarrow (SP) - \0001

Push high half of return address

 $PC \leftarrow (PC) + rel$

Load PC with start address of requested subroutine

Description

The program counter is incremented by 2 from the opcode address (so it points to the opcode of the next instruction which will be the return address). The least significant byte of the contents of the program counter (low-order return address) is pushed onto the stack. The stack pointer is then decremented by 1. The most significant byte of the contents of the program counter (high-order return address) is pushed onto the stack. The stack pointer is then decremented by 1. A branch then occurs to the location specified by the branch offset. See the [BRA](#) instruction for further details of the execution of the branch.

CBEQ

Compare and Branch if Equal

CBEQ

Operation

For DIR or IMM modes: if (A) = (M), $PC \leftarrow (PC) + \$0003 + rel$
Or for IX+ mode: if (A) = (M); $PC \leftarrow (PC) + \$0002 + rel$
Or for SP1 mode: if (A) = (M); $PC \leftarrow (PC) + \$0004 + rel$
Or for CBEQX: if (X) = (M); $PC \leftarrow (PC) + \$0003 + rel$

Description

CBEQ compares the operand with the accumulator (or index register for CBEQX instruction) against the contents of a memory location and causes a branch if the register (A or X) is equal to the memory contents. The CBEQ instruction combines CMP and BEQ for faster table lookup routines and condition codes are not changed.

The IX+ variation of the CBEQ instruction compares the operand addressed by H:X to A and causes a branch if the operands are equal. H:X is then incremented regardless of whether a branch is taken. The IX1+ variation of CBEQ operates the same way except that an 8-bit offset is added to H:X to form the effective address of the operand.

Instruction Set

CLC

Clear Carry Bit

CLC

Operation

C bit \leftarrow 0

Description

Clears the C bit in the CCR. CLC may be used to set up the C bit prior to a shift or rotate instruction that involves the C bit. The C bit can also be used to pass status information between a subroutine and the calling program.

CLI**Clear Interrupt Mask Bit****CLI****Operation** $I \text{ bit} \leftarrow 0$ **Description**

Clears the interrupt mask bit in the CCR. When the I bit is clear, interrupts are enabled. The I bit actually changes to zero at the end of the cycle where the CLI instruction executes. This is too late to recognize an interrupt that arrived before or during the CLI instruction so if interrupts were previously disabled, the next instruction after a CLI will always be executed even if there was an interrupt pending prior to execution of the CLI instruction.

CMP

Compare Accumulator with Memory

CMP

Operation

(A) – (M)

Description

Compares the contents of A to the contents of M and sets the condition codes, which may then be used for arithmetic (signed or unsigned) and logical conditional branching. The contents of both A and M are unchanged.

Condition Codes and Boolean Formulae

V			H	I	N	Z	C
↑	1	1	—	—	↑	↑	↑

V: $A7\&\overline{M7}\&\overline{R7} \mid \overline{A7}\&\overline{M7}\&\overline{R7}$

Set if a two's complement overflow resulted from the operation; cleared otherwise. Literally read, an overflow condition occurs if a positive number is subtracted from a negative number with a positive result, or, if a negative number is subtracted from a positive number with a negative result.

N: R7

Set if MSB of result is 1; cleared otherwise

Z: $\overline{R7}\&\overline{R6}\&\overline{R5}\&\overline{R4}\&\overline{R3}\&\overline{R2}\&\overline{R1}\&\overline{R0}$

Set if result is \$00; cleared otherwise

C: $\overline{A7}\&\overline{M7} \mid \overline{M7}\&\overline{R7} \mid \overline{R7}\&\overline{A7}$

Set if the unsigned value of the contents of memory is larger than the unsigned value of the accumulator; cleared otherwise

DAA

Decimal Adjust Accumulator

DAA

Operation $(A)_{10}$ **Description**

Adjusts the contents of the accumulator and the state of the CCR carry bit after an ADD or ADC operation involving binary-coded decimal (BCD) values, so that there is a correct BCD sum and an accurate carry indication. The state of the CCR half carry bit affects operation. Refer to [Table 5-2](#) for details of operation.

DAA	INH	72		2

The DAA description continues next page.

DAA

Decimal Adjust Accumulator (Continued)

DAA

Table 5-2 shows DAA operation for all legal combinations of input operands. Columns 1–4 represent the results of ADC or ADD operations on BCD operands. The correction factor in column 5 is added to the accumulator to restore the result of an operation on two BCD operands to a valid BCD value and to set or clear the C bit. All values in this table are hexadecimal.

Table 5-2. DAA Function Summary

1	2	3	4	5	6
Initial C-Bit Value	Value of A[7:4]	Initial H-Bit Value	Value of A[3:0]	Correction Factor	Corrected C-Bit Value
0	0–9	0	0–9	00	0
0	0–8	0	A–F	06	0
0	0–9	1	0–3	06	0
0	A–F	0	0–9	60	1
0	9–F	0	A–F	66	1
0	A–F	1	0–3	66	1
1	0–2	0	0–9	60	1
1	0–2	0	A–F	66	1
1	0–3	1	0–3	66	1

DBNZ

Decrement and Branch if Not Zero

DBNZ

Operation

$$A \leftarrow (A) - \$01$$

Or $M \leftarrow (M) - \$01$

Or $X \leftarrow (X) - \$01$

For DIR or IX1 modes: $PC \leftarrow (PC) + \$0003 + rel$ if (result) $\neq 0$

Or for INH or IX modes: $PC \leftarrow (PC) + \$0002 + rel$ if (result) $\neq 0$

Or for SP1 mode: $PC \leftarrow (PC) + \$0004 + rel$ if (result) $\neq 0$

Description

Subtract 1 from the contents of A, M, or X; then branch using the relative offset if the result of the subtraction is not \$00. DBNZX only affects the low order eight bits of the H:X index register pair; the high-order byte (H) is not affected.

Instruction Set

DEC

Decrement

DEC

Operation

$A \leftarrow (A) - \$01$
Or $X \leftarrow (X) - \$01$
Or $M \leftarrow (M) - \$01$

Description

Subtract 1 from the contents of A, X, or M. The V, N, and Z bits in the CCR are set or cleared according to the results of this operation. The C bit in the CCR is not affected; therefore, the BLS, BLO, BHS, and BHI branch instructions are not useful following a DEC instruction.

DECX only affects the low-order byte of index register pair (H:X). To decrement the full 16-bit index register pair (H:X), use AIX # -1.

Condition Codes
and Boolean
Formulae

V			H	I	N	Z	C

DEX is recognized by assemblers as being equivalent to DECX.

DIV

Divide

DIV

Operation

$$A \leftarrow (H:A) \div (X); H \leftarrow \text{Remainder}$$

Description

Divides a 16-bit unsigned dividend contained in the concatenated registers H and A by an 8-bit divisor contained in X. The quotient is placed in A, and the remainder is placed in H. The divisor is left unchanged.

An overflow (quotient > \$FF) or divide-by-0 sets the C bit, and the quotient and remainder are indeterminate.

INC

Increment

INC

Operation

$A \leftarrow (A) + \$01$
Or $X \leftarrow (X) + \$01$
Or $M \leftarrow (M) + \$01$

Description

Add 1 to the contents of A, X, or M. The V, N, and Z bits in the CCR are set or cleared according to the results of this operation. The C bit in the CCR is not affected; therefore, the BLS, BLO, BHS, and BHI branch instructions are not useful following an INC instruction.

INCX only affects the low-order byte of index register pair (H:X). To increment the full 16-bit index register pair (H:X), use AIX #1.

INX is recognized by assemblers as being equivalent to INCX.

Instruction Set

JMP

Jump

JMP

Operation

PC ← effective address

Description

A jump occurs to the instruction stored at the effective address. The effective address is obtained according to the rules for extended, direct, or indexed addressing.

Condition Codes and Boolean Formulae

None affected

JMP <i>,X</i>	IX	FC		3

JSR

Jump to Subroutine

JSR

Operation

$$PC \leftarrow (PC) + n;$$

$$n = 1, 2, \text{ or } 3 \text{ depending on address mode}$$

 Push (PCL); $SP \leftarrow (SP) - \$0001$ Push low half of return address

 Push (PCH); $SP \leftarrow (SP) - \$0001$ Push high half of return address

 $PC \leftarrow \text{effective address}$ Load PC with start address of
requested subroutine

Description

The program counter is incremented by n so that it points to the opcode of the next instruction that follows the JSR instruction ($n = 1, 2, \text{ or } 3$ depending on the addressing mode). The PC is then pushed onto the stack, eight bits at a time, least significant byte first. The stack pointer points to the next empty location on the stack. A jump occurs to the instruction stored at the effective address. The effective address is obtained according to the rules for extended, direct, or indexed addressing.

Instruction Set

LDA

Load Accumulator from Memory

LDA

Operation

 $A \leftarrow (M)$

Description

Loads the contents of the specified memory location into A. The N and Z condition codes are set or cleared according to the loaded data; V is cleared. This allows conditional branching after the load without having to perform a separate test or compare.

Condition Codes and Boolean Formulae

V		H		I	N	Z	C

LSL

Logical Shift Left (Same as ASL)

LSL

Operation

Description

Shifts all bits of the A, X, or M one place to the left. Bit 0 is loaded with a 0. The C bit in the CCR is loaded from the most significant bit of A, X, or M.

Condition Codes and Boolean Formulae

V			H	I	N	Z	C
↑	1	1	—	—	↑	↑	↑

V: $R7 \oplus b7$

Set if the exclusive-OR of the resulting N and C flags is 1; cleared otherwise

N: R7

Set if MSB of result is 1; cleared otherwise

Z: $\overline{R7} \& \overline{R6} \& \overline{R5} \& \overline{R4} \& \overline{R3} \& \overline{R2} \& \overline{R1} \& \overline{R0}$

Set if result is \$00; cleared otherwise

MOV

Move

MOV

Operation

 $(M)_{\text{Destination}} \leftarrow (M)_{\text{Source}}$

Description

Moves a byte of data from a source address to a destination address. Data is examined as it is moved, and condition codes are set. Source data is not changed. The accumulator is not affected.

The four addressing modes for the MOV instruction are:

1. IMM/DIR moves an immediate byte to a direct memory location.
2. DIR/DIR moves a direct location byte to another direct location.
3. IX+/DIR moves a byte from a location addressed by H:X to a direct location. H:X is incremented after the move.
4. DIR/IX+ moves a byte from a direct location to one addressed by H:X. H:X is incremented after the move.

Instruction Set

MUL

Unsigned Multiply

MUL

Operation

$$X:A \leftarrow (X) \times (A)$$

Description

Multiplies the 8-bit value in X (index register low) by the 8-bit value in the accumulator to obtain a 16-bit unsigned result in the concatenated index register and accumulator. After the operation, X contains the upper eight bits of the 16-bit result and A contains the lower eight bits of the result.

NEG

Negate (Two's Complement)

NEG

Operation

 $A \leftarrow - (A)$ **Or** $X \leftarrow - (X)$ **Or** $M \leftarrow - (M);$

this is equivalent to subtracting A, X, or M from \$00

Description

Replaces the contents of A, X, or M with its two's complement. Note that the value \$80 is left unchanged.

Condition Codes
and Boolean
Formulae

V			H	I	N	Z	C
↑	1	1	—	—	↑	↑	↑

V: M7&R7

Set if a two's complement overflow resulted from the operation; cleared otherwise. Overflow will occur only if the operand is \$80 before the operation.

N: R7

Set if MSB of result is 1; cleared otherwise

Z: $\overline{R7} \& \overline{R6} \& \overline{R5} \& \overline{R4} \& \overline{R3} \& \overline{R2} \& \overline{R1} \& \overline{R0}$

Set if result is \$00; cleared otherwise

C: $R7|R6|R5|R4|R3|R2|R1|R0$

Set if there is a borrow in the implied subtraction from 0; cleared otherwise. The C bit will be set in all cases except when the contents of A, X, or M was \$00 prior to the NEG operation.

ROL

Rotate Left through Carry

ROL

Operation

Description

Shifts all bits of A, X, or M one place to the left. Bit 0 is loaded from the C bit. The C bit is loaded from the most significant bit of A, X, or M. The rotate instructions include the carry bit to allow extension of the shift and rotate instructions to multiple bytes. For example, to shift a 24-bit value left one bit, the sequence (ASL LOW, ROL MID, ROL HIGH) could be used, where LOW, MID, and HIGH refer to the low-order, middle, and high-order bytes of the 24-bit value, respectively.

RSP

Reset Stack Pointer

RSP

Operation

$$SP \leftarrow \$FF$$

Description

In most M68HC05 MCUs, RAM only goes to \$00FF. In most HC08s, however, RAM extends beyond \$00FF. Therefore, do not locate the stack in direct address space which is more valuable for commonly accessed variables. In new HC08 programs, it is more appropriate to initialize the stack pointer to the address of the last location (highest address) in the on-chip RAM, shortly after reset. This code segment demonstrates a typical method for initializing SP.

```
LDHX    #ram_end+1    ; Point at next addr past RAM
TXS                      ; SP <- (H:X)-1
```

		Opcode	Operand(s)	
RTI	INH	80		7

RTS

Return from Subroutine

RTS

Operation

$$SP \leftarrow SP + \$0001; \text{pull (PCH) Restore PCH from stack}$$

$$SP \leftarrow SP + \$0001; \text{pull (PCL) Restore PCL from stack}$$

Description

The stack pointer is incremented by 1. The contents of the byte of memory that is pointed to by the stack pointer are loaded into the high-order byte of the program counter. The stack pointer is again incremented by 1. The contents of the byte of memory that are pointed to by the stack pointer are loaded into the low-order eight bits of the program counter. Program execution resumes at the address that was just restored from the stack.

SBC

Subtract with Carry

SBC

Operation

$$A \leftarrow (A) - (M) - (C)$$

Description

Subtracts the contents of M and the contents of the C bit of the CCR from the contents of A and places the result in A. This is useful for multi-precision subtract algorithms involving operands with more than eight bits.

Condition Codes and Boolean Formulae

V			H	I	N	Z	C
↑	1	1	—	—	↑	↑	↑

$$V: A7\&\overline{M7}\&\overline{R7} \mid \overline{A7}\&M7\&R7$$

Set if a two's complement overflow resulted from the operation; cleared otherwise. Literally read, an overflow condition occurs if a positive number is subtracted from a negative number with a positive result, or, if a negative number is subtracted from a positive number with a negative result.

$$N: R7$$

Set if MSB of result is 1; cleared otherwise

$$Z: \overline{R7}\&\overline{R6}\&\overline{R5}\&\overline{R4}\&\overline{R3}\&\overline{R2}\&\overline{R1}\&\overline{R0}$$

Set if result is \$00; cleared otherwise

$$C: \overline{A7}\&M7 \mid M7\&R7 \mid R7\&\overline{A7}$$

Set if the unsigned value of the contents of memory plus the previous carry are larger than the unsigned value of the accumulator; cleared otherwise

SEC

Set Carry Bit

SEC

Operation

C bit \leftarrow 1

Description

Sets the C bit in the condition code register (CCR). SEC may be used to set up the C bit prior to a shift or rotate instruction that involves the C bit.

Instruction Set

SEI**Set Interrupt Mask Bit****SEI****Operation**I bit \leftarrow 1**Description**

Sets the interrupt mask bit in the condition code register (CCR). The microprocessor is inhibited from responding to interrupts while the I bit is set. The I bit actually changes at the end of the cycle where SEI executed. This is too late to stop an interrupt that arrived during execution of the SEI instruction so it is possible that an interrupt request could be serviced after the SEI instruction before the next instruction after SEI is executed. The global I-bit interrupt mask takes effect before the next instruction can be completed.

STA

Store Accumulator in Memory

STA

Operation

 $M \leftarrow (A)$

Description

Stores the contents of A in memory. The contents of A remain unchanged. The N condition code is set if the most significant bit of A is set, the Z bit is set if A was \$00, and V is cleared. This allows conditional branching after the store without having to do a separate test or compare.

Instruction Set

STHX

Store Index Register

STHX

Operation

$$(M:M + \$0001) \leftarrow (H:X)$$

Description

Stores the contents of H in memory location M and then the contents of X into the next memory location (M + \$0001). The N condition code bit is set if the most significant bit of H was set, the Z bit is set if the value of H:X was \$0000, and V is cleared. This allows conditional branching after the store without having to do a separate test or compare.

STOP

Enable $\overline{\text{IRQ}}$ Pin, Stop Oscillator

STOP

Operation

$\text{I bit} \leftarrow 0$; stop oscillator

Description

Reduces power consumption by eliminating all dynamic power dissipation. (See module documentation for module reactions to STOP instruction.) The external interrupt pin is enabled and the I bit in the condition code register (CCR) is cleared to enable the external interrupt. Finally, the oscillator is inhibited to put the MCU into the STOP condition.

When either the $\overline{\text{RESET}}$ pin or $\overline{\text{IRQ}}$ pin goes low, the oscillator is enabled. A delay of 4095 processor clock cycles is imposed allowing the oscillator to stabilize. The reset vector or interrupt request vector is fetched and the associated service routine is executed.

External interrupts are enabled after a STOP command.

SWI

Software Interrupt

SWI

Operation

$PC \leftarrow (PC) + \$0001$ Increment PC to return address
 $Push(PCL); SP \leftarrow (SP) - \0001 Push low half of return address
 $Push(PCH); SP \leftarrow (SP) - \0001 Push high half of return address
 $Push(X); SP \leftarrow (SP) - \0001 Push index register on stack
 $Push(A); SP \leftarrow (SP) - \0001 Push A on stack
 $Push(CCR); SP \leftarrow (SP) - \0001 Push CCR on stack
 $I \text{ bit} \leftarrow 1$ Mask further interrupts
 $PCH \leftarrow (\$FFFC)$ Vector fetch (high byte)
 $PCL \leftarrow (\$FFFD)$ Vector fetch (low byte)

Description

The program counter (PC) is incremented by 1 to point at the instruction after the SWI. The PC, index register, and accumulator are pushed onto the stack. The condition code register (CCR) bits are then pushed onto the stack, with bits V, H, I, N, Z, and C going into bit positions 7 and 4–0. Bit positions 6 and 5 contain 1s. The stack pointer is decremented by 1 after each byte of data is stored on the stack. The interrupt mask bit is then set. The program counter is then loaded with the address stored in the SWI vector located at memory locations \$FFFC and \$FFFD. This instruction is not maskable by the I bit.

TAP

Transfer Accumulator to Processor Status Byte

TAP

Operation

$CCR \leftarrow (A)$

Description

Transfers the contents of A to the condition code register (CCR). The contents of A are unchanged. If this instruction causes the I bit to change from 0 to 1, a one bus cycle delay is imposed before interrupts become masked. This assures that the next instruction after a TAP instruction will always be executed even if an interrupt became pending during the TAP instruction.

Condition Codes and Boolean Formulae

V			H	I	N	Z	C
↓	1	1	↓	↓	↓	↓	↓

Set or cleared according to the value that was in the accumulator.

Instruction Set

WAIT

Enable Interrupts; Stop Processor

WAIT

Operation

I bit \leftarrow 0; inhibit CPU clocking until interrupted

Description

Reduces power consumption by eliminating dynamic power dissipation in some portions of the MCU. The timer, the timer prescaler, and the on-chip peripherals continue to operate (if enabled) because they are potential sources of an interrupt. Wait causes enabling of interrupts by clearing the I bit in the CCR and stops clocking of processor circuits.

Interrupts from on-chip peripherals may be enabled or disabled by local control bits prior to execution of the WAIT instruction.

When either the $\overline{\text{RESET}}$ or $\overline{\text{IRQ}}$ pin goes low or when any on-chip system requests interrupt service, the processor clocks are enabled, and the reset, $\overline{\text{IRQ}}$, or other interrupt service request is processed.

6.2 Introduction

The M68HC08 Family instruction set is an extension of the M68HC05 Family instruction set. This section contains code examples for the instructions unique to the M68HC08 Family.

6.3 M68HC08 Unique Instructions

This is a list of the instructions unique to the M68HC08 Family.

- Add Immediate Value (Signed) to Stack Pointer (AIS)
- Add Immediate Value (Signed) to Index Register (AIX)
- Branch if Greater Than or Equal To (BGE)
- Branch if Greater Than (BGT)
- Branch if Less Than or Equal To (BLE)
- Branch if Less Than (BLT)
- Compare and Branch if Equal (CBEQ)
- Compare Accumulator with Immediate, Branch if Equal (CBEQA)
- Compare Index Register Low with Immediate, Branch if Equal (CBEQX)
- Clear Index Register High (CLRH)
- Compare Index Register with Immediate Value (CPHX)
- Decimal Adjust Accumulator (DAA)
- Decrement and Branch if Not Zero (DBNZ)
- Divide (DIV)

- Load Index Register with Immediate Value (LDHX)
- Move (MOV)
- Nibble Swap Accumulator (NSA)
- Push Accumulator onto Stack (PSHA)
- Push Index Register High onto Stack (PSHH)
- Push Index Register Low onto Stack (PSHX)
- Pull Accumulator from Stack (PULA)
- Pull Index Register High from Stack (PULH)
- Pull Index Register Low from Stack (PULX)
- Store Index Register (STHX)
- Transfer Accumulator to Condition Code Register (TAP)
- Transfer Condition Code Register to Accumulator (TPA)
- Transfer Stack Pointer to Index Register (TSX)
- Transfer Index Register to Stack Pointer (TXS)

6.4 Code Examples

The following pages contain code examples for the instructions unique to the M68HC08 Family.

	DIV		;Resolve remainder
	STA	QUOTIENT2+1	

*
 *

DIV

Divide
(Continued)

DIV

* 3) 8/8 fractional divide > 16-bit fractional quotient
 * Performs an unsigned fractional divide of an 8-bit dividend
 * in H by the 8-bit divisor in X. A must be cleared. The
 * quotient is placed into A and the remainder in H. The
 * remainder may be further resolved by executing additional
 * DIV instructions as shown below.
 * The radix point is assumed to be in the same place for both
 * the dividend and the divisor. The radix point is to the
 * left of the MS bit of the quotient. An overflow will occur
 * when the dividend is greater than or equal to the divisor.
 * The quotient is an unsigned binary weighted fraction with
 * a range of \$00 to \$FF (0.9961).
 *

Label	Operation	Operand	Comments

	CLRA		
	DIV		;Resolve remainder
	STA	QUOTIENT3+1	

*
 *
 * 4) Unbounded 16/8 integer divide
 * This algorithm performs the equivalent of long division.
 * The initial divide is an 8/8 (no overflow possible).
 * Subsequent divide are 16/8 using the remainder from the
 * previous divide operation (no overflow possible).
 * The DIV instruction does not corrupt the divisor and leaves
 * the remainder in H, the optimal position for successive
 * divide operations. The algorithm may be extended to any
 * precision of dividend by performing additional divides.
 * This, of course, includes resolving the remainder of a
 * divide operation into a fractional result as shown below.
 *

Glossary

\$xxxx — The digits following the “\$” are in hexadecimal format.

#xxxx — The digits following the “#” indicate an immediate operand.

A — Accumulator. See “accumulator.”

accumulator (A) — An 8-bit general-purpose register in the CPU08.
The CPU08 uses the accumulator to hold operands and results of arithmetic and non-arithmetic operations.

address bus — The set of conductors used to select a specific memory location so that the CPU can write information into the memory location or read its contents.

addressing mode — The way that the CPU obtains (addresses) the information needed to complete an instruction. The M68HC08 CPU has 16 addressing modes.

algorithm — A set of specific procedures by which a solution is obtained in a finite number of steps, often used in numerical calculation.

ALU — Arithmetic logic unit. See “arithmetic logic unit.”

arithmetic logic unit (ALU) — The portion of the CPU of a computer where mathematical and logical operations take place. Other circuitry decodes each instruction and configures the ALU to perform the necessary arithmetic or logical operations at each step of an instruction.

assembly language — A method used by programmers for representing machine instructions (binary data) in a more convenient form. Each machine instruction is given a simple, short name, called a mnemonic (or memory aid), which has a

one-to-one correspondence with the machine instruction. The mnemonics are translated into an object code program that a microcontroller can use.

ASCII — American Standard Code for Information Interchange. A widely accepted correlation between alphabetic and numeric characters and specific 7-bit binary numbers.

asynchronous — Refers to circuitry and operations without common clock signals.

BCD — Binary-coded decimal. See “binary-coded decimal.”

binary — The binary number system using 2 as its base and using only the digits 0 and 1. Binary is the numbering system used by computers because any quantity can be represented by a series of 1s and 0s. Electrically, these 1s and 0s are represented by voltage levels of approximately V_{DD} (input) and V_{SS} (ground), respectively.

binary-coded decimal (BCD) — A notation that uses binary values to represent decimal quantities. Each BCD digit uses four binary bits. Six of the possible 16 binary combinations are considered illegal.

bit — A single binary digit. A bit can hold a single value of 0 or 1.

Boolean — A mathematical system of representing logic through a series of algebraic equations that can only be true or false, using operators such as AND, OR, and NOT.

branch instructions — Computer instructions that cause the CPU to continue processing at a memory location other than the next sequential address. Most branch instructions are conditional. That is, the CPU continues to the next sequential address (no branch) if a condition is false, or continue to some other address (branch) if the condition is true.

bus — A collection of logic lines (conductor paths) used to transfer data.

byte — A set of exactly eight binary bits.

C — Abbreviation for carry/borrow in the condition code register of the CPU08. The CPU08 sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the C flag (as in bit test and branch instructions and shifts and rotates).

CCR — Abbreviation for condition code register in the CPU08. See “condition code register.”

central processor unit (CPU) — The primary functioning unit of any computer system. The CPU controls the execution of instructions.

checksum — A value that results from adding a series of binary numbers. When exchanging information between computers, a checksum gives an indication about the integrity of the data transfer. If values were transferred incorrectly, it is unlikely that the checksum would match the value that was expected.

clear — To establish logic 0 state on a bit or bits; the opposite of “set.”

clock — A square wave signal used to sequence events in a computer.

condition code register (CCR) — An 8-bit register in the CPU08 that contains the interrupt mask bit and five bits (flags) that indicate the results of the instruction just executed.

control unit — One of two major units of the CPU. The control unit contains logic functions that synchronize the machine and direct various operations. The control unit decodes instructions and generates the internal control signals that perform the requested operations. The outputs of the control unit drive the execution unit, which contains the arithmetic logic unit (ALU), CPU registers, and bus interface.

CPU — Central processor unit. See “central processor unit.”

CPU08 — The central processor unit of the M68HC08 Family.

CPU cycles — A CPU clock cycle is one period of the internal bus-rate clock, normally derived by dividing a crystal oscillator source by two or more so the high and low times are equal. The length of time required to execute an instruction is measured in CPU clock cycles.

CPU registers — Memory locations that are wired directly into the CPU logic instead of being part of the addressable memory map. The CPU always has direct access to the information in these registers. The CPU registers in an M68HC08 are:

- A (8-bit accumulator)
- H:X (16-bit accumulator)
- SP (16-bit stack pointer)
- PC (16-bit program counter)
- CCR (condition code register containing the V, H, I, N, Z, and C bits)

cycles — See “CPU cycles.”

data bus — A set of conductors used to convey binary information from a CPU to a memory location or from a memory location to a CPU.

decimal — Base 10 numbering system that uses the digits zero through nine.

direct address — Any address within the first 256 addresses of memory (\$0000–\$00FF). The high-order byte of these addresses is always \$00. Special instructions allow these addresses to be accessed using only the low-order byte of their address. These instructions automatically fill in the assumed \$00 value for the high-order byte of the address.

direct addressing mode — Direct addressing mode uses a program-supplied value for the low-order byte of the address of an operand. The high-order byte of the operand address is assumed to be \$00 and so it does not have to be explicitly specified. Most direct addressing mode instructions can access any of the first 256 memory addresses.

direct memory access (DMA) — One of a number of modules that handle a variety of control functions in the modular M68HC08 Family. The DMA can perform interrupt-driven and software-initiated data transfers between any two CPU-addressable locations. Each DMA channel can independently transfer data between any addresses in the memory map. DMA transfers reduce CPU overhead required for data movement interrupts.

direct page — The first 256 bytes of memory (\$0000–\$00FF); also called page 0.

DMA — Direct memory access. See “direct memory access.”

EA — Effective address. See “effective address.”

effective address (EA) — The address where an instruction operand is located. The addressing mode of an instruction determines how the CPU calculates the effective address of the operand.

EPROM — Erasable, programmable, read-only memory. A non-volatile type of memory that can be erased by exposure to an ultraviolet light source.

EU — Execution unit. See “execution unit.”

execution unit (EU) — One of the two major units of the CPU containing the arithmetic logic unit (ALU), CPU registers, and bus interface. The outputs of the control unit drive the execution unit.

extended addressing mode — In this addressing mode, the high-order byte of the address of the operand is located in the next memory location after the opcode. The low-order byte of the operand address is located in the second memory location after the opcode. Extended addressing mode instructions can access any address in a 64-Kbyte memory map.

H — Abbreviation for the upper byte of the 16-bit index register (H:X) in the CPU08.

H — Abbreviation for “half-carry” in the condition code register of the CPU08. This bit indicates a carry from the low-order four bits of the accumulator value to the high-order four bits. The half-carry bit is required for binary-coded decimal arithmetic operations. The decimal adjust accumulator (DAA) instruction uses the state of the H and C flags to determine the appropriate correction factor.

hexadecimal — Base 16 numbering system that uses the digits 0 through 9 and the letters A through F. One hexadecimal digit can exactly represent a 4-bit binary value. Hexadecimal is used by people to represent binary values because a 2-digit number is easier to use than the equivalent 8-digit number.

high order — The leftmost digit(s) of a number; the opposite of low order.

H:X — Abbreviation for the 16-bit index register in the CPU08. The upper byte of H:X is called H. The lower byte is called X. In the indexed addressing modes, the CPU uses the contents of H:X to determine the effective address of the operand. H:X can also serve as a temporary data storage location.

I — Abbreviation for “interrupt mask bit” in the condition code register of the CPU08. When I is set, all interrupts are disabled. When I is cleared, interrupts are enabled.

immediate addressing mode — In immediate addressing mode, the operand is located in the next memory location(s) after the opcode. The immediate value is one or two bytes, depending on the size of the register involved in the instruction.

index register (H:X) — A 16-bit register in the CPU08. The upper byte of H:X is called H. The lower byte is called X. In the indexed addressing modes, the CPU uses the contents of H:X to determine the effective address of the operand. H:X can also serve as a temporary data storage location.

indexed addressing mode — Indexed addressing mode instructions access data with variable addresses. The effective address of the operand is determined by the current value of the H:X register added to a 0-, 8-, or 16-bit value (offset) in the

instruction. There are separate opcodes for 0-, 8-, and 16-bit variations of indexed mode instructions, and so the CPU knows how many additional memory locations to read after the opcode.

indexed, post increment addressing mode — In this addressing mode, the effective address of the operand is determined by the current value of the index register, added to a 0- or 8-bit value (offset) in the instruction, after which the index register is incremented. Operands with variable addresses can be addressed with the 8-bit offset instruction.

inherent addressing mode — The inherent addressing mode has no operand because the opcode contains all the information necessary to carry out the instruction. Most inherent instructions are one byte long.

input/output (I/O) — Input/output interfaces between a computer system and the external world. A CPU reads an input to sense the level of an external signal and writes to an output to change the level on an external signal.

instructions — Instructions are operations that a CPU can perform. Instructions are expressed by programmers as assembly language mnemonics. A CPU interprets an opcode and its associated operand(s) and instruction(s).

instruction set — The instruction set of a CPU is the set of all operations that the CPU can perform. An instruction set is often represented with a set of shorthand mnemonics, such as LDA, meaning “load accumulator (A).” Another representation of an instruction set is with a set of opcodes that are recognized by the CPU.

interrupt — Interrupts provide a means to temporarily suspend normal program execution so that the CPU is freed to service sets of instructions in response to requests (interrupts) from peripheral devices. Normal program execution can be resumed later from its original point of departure. The CPU08 can process up to 128 separate interrupt sources, including a software interrupt (SWI).

I/O — Input/output. See “input/output.”

IRQ — Interrupt request. The overline indicates an active-low signal.

least significant bit (LSB) — The rightmost digit of a binary value; the opposite of most significant bit (MSB).

logic 1 — A voltage level approximately equal to the input power voltage (V_{DD}).

logic 0 — A voltage level approximately equal to the ground voltage (V_{SS}).

low order — The rightmost digit(s) of a number; the opposite of high order.

LS — Least significant.

LSB — Least significant bit. See “least significant bit.”

M68HC08 — The Motorola Family of 8-bit MCUs.

machine codes — The binary codes processed by the CPU as instructions. Machine code includes both opcodes and operand data.

MCU — Microcontroller unit. See “microcontroller unit.”

memory location — In the M68HC08, each memory location holds one byte of data and has a unique address. To store information into a memory location, the CPU places the address of the location on the address bus, the data information on the data bus, and asserts the write signal. To read information from a memory location, the CPU places the address of the location on the address bus and asserts the read signal. In response to the read signal, the selected memory location places its data onto the data bus.

memory map — A pictorial representation of all memory locations in a computer system.

memory-to-memory addressing mode — In this addressing mode, the accumulator has been eliminated from the data transfer process, thereby reducing execution cycles. This addressing mode, therefore, provides rapid data transfers because it does

not use the accumulator and associated load and store instructions. There are four memory-to-memory addressing mode instructions. Depending on the instruction, operands are found in the byte following the opcode, in a direct page location addressed by the byte immediately following the opcode, or in a location addressed by the index register.

microcontroller unit (MCU) — A complete computer system, including a CPU, memory, a clock oscillator, and input/output (I/O) on a single integrated circuit.

mnemonic — Three to five letters that represent a computer operation. For example, the mnemonic form of the “load accumulator” instruction is LDA.

most significant bit (MSB) — The leftmost digit of a binary value; the opposite of least significant bit (LSB).

MS — Abbreviation for “most significant.”

MSB — Most significant bit. See “most significant bit.”

N — Abbreviation for “negative,” a bit in the condition code register of the CPU08. The CPU sets the negative flag when an arithmetic operation, logical operation, or data manipulation produces a negative result.

nibble — Half a byte; four bits.

object code — The output from an assembler or compiler that is itself executable machine code or is suitable for processing to produce executable machine code.

one — A logic high level, a voltage level approximately equal to the input power voltage (V_{DD}).

one's complement — An infrequently used form of signed binary numbers. Negative numbers are simply the complement of their positive counterparts. One's complement is the result of a bit-by-bit complement of a binary word: All 1s are changed to 0s and all 0s changed to 1s. One's complement is two's complement without the increment.

opcode — A binary code that instructs the CPU to do a specific operation in a specific way.

operand — The fundamental quantity on which a mathematical operation is performed. Usually a statement consists of an operator and an operand. The operator may indicate an add instruction; the operand therefore will indicate what is to be added.

oscillator — A circuit that produces a constant frequency square wave that is used by the computer as a timing and sequencing reference.

page 0 — The first 256 bytes of memory (\$0000–\$00FF). Also called direct page.

PC — Program counter. See “program counter.”

pointer — Pointer register. An index register is sometimes called a pointer register because its contents are used in the calculation of the address of an operand, and therefore “points” to the operand.

program — A set of computer instructions that cause a computer to perform a desired operation or operations.

programming model — The registers of a particular CPU.

program counter (PC) — A 16-bit register in the CPU08. The PC register holds the address of the next instruction or operand that the CPU will use.

pull — The act of reading a value from the stack. In the M68HC08, a value is pulled by the following sequence of operations. First, the stack pointer register is incremented so that it points to the last value saved on the stack. Next, the value at the address contained in the stack pointer register is read into the CPU.

push — The act of storing a value at the address contained in the stack pointer register and then decrementing the stack pointer so that it points to the next available stack location.

random access memory (RAM) — A type of memory that can be read or written by the CPU. The contents of a RAM memory location remain valid until the CPU writes a different value or until power is turned off.

RAM — Random access memory. See “random-access memory.”

read — To transfer the contents of a memory location to the CPU.

read-only memory — A type of memory that can be read but cannot be changed (written) by the CPU. The contents of ROM must be specified before manufacturing the MCU.

registers — Memory locations wired directly into the CPU logic instead of being part of the addressable memory map. The CPU always has direct access to the information in these registers. The CPU registers in an M68HC08 are:

- A (8-bit accumulator)
- (H:X) (16-bit index register)
- SP (16-bit stack pointer)
- PC (16-bit program counter)
- CCR (condition code register containing the V, H, I, N, Z, and C bits)

Memory locations that hold status and control information for on-chip peripherals are called input/output (I/O) and control registers.

relative addressing mode — Relative addressing mode is used to calculate the destination address for branch instructions. If the branch condition is true, the signed 8-bit value after the opcode is added to the current value of the program counter to get the address where the CPU will fetch the next instruction. If the branch condition is false, the effective address is the content of the program counter.

reset — Reset is used to force a computer system to a known starting point and to force on-chip peripherals to known starting conditions.

ROM — Read-only memory. See “read-only memory.”

set — To establish a logic 1 state on a bit or bits; the opposite of “clear.”

signed — A form of binary number representation accommodating both positive and negative numbers. The most significant bit is used to indicate whether the number is positive or negative, normally zero for positive and one for negative, and the other seven bits indicate the magnitude.

SIM — System integration module. See “system integration module.”

SP — Stack pointer. See “stack pointer.”

stack — A mechanism for temporarily saving CPU register values during interrupts and subroutines. The CPU maintains this structure with the stack pointer (SP) register, which contains the address of the next available (empty) storage location on the stack. When a subroutine is called, the CPU pushes (stores) the low-order and high-order bytes of the return address on the stack before starting the subroutine instructions. When the subroutine is done, a return from subroutine (RTS) instruction causes the CPU to recover the return address from the stack and continue processing where it left off before the subroutine. Interrupts work in the same way except that all CPU registers are saved on the stack instead of just the program counter.

stack pointer (SP) — A 16-bit register in the CPU08 containing the address of the next available (empty) storage on the stack.

stack pointer addressing mode — Stack pointer (SP) addressing mode instructions operate like indexed addressing mode instructions except that the offset is added to the stack pointer instead of the index register (H:X). The effective address of the operand is formed by adding the unsigned byte(s) in the stack pointer to the unsigned byte(s) following the opcode.

subroutine — A sequence of instructions to be used more than once in the course of a program. The last instruction in a subroutine is a return-from-subroutine (RTS) instruction. At each place in the main program where the subroutine instructions are needed, a jump or branch to subroutine (JSR or BSR) instruction is used to

call the subroutine. The CPU leaves the flow of the main program to execute the instructions in the subroutine. When the RTS instruction is executed, the CPU returns to the main program where it left off.

synchronous — Refers to two or more things made to happen simultaneously in a system by means of a common clock signal.

system integration module (SIM) — One of a number of modules that handle a variety of control functions in the modular M68HC08 Family. The SIM controls mode of operation, resets and interrupts, and system clock generation.

table — A collection or ordering of data (such as square root values) laid out in rows and columns and stored in a computer memory as an array.

two's complement — A means of performing binary subtraction using addition techniques. The most significant bit of a two's complement number indicates the sign of the number (1 indicates negative). The two's complement negative of a number is obtained by inverting each bit in the number and then adding 1 to the result.

unsigned — Refers to a binary number representation in which all numbers are assumed positive. With signed binary, the most significant bit is used to indicate whether the number is positive or negative, normally 0 for positive and 1 for negative, and the other seven bits are used to indicate the magnitude.

variable — A value that changes during the course of executing a program.

word — Two bytes or 16 bits, treated as a unit.

write — The transfer of a byte of data from the CPU to a memory location.

X — Abbreviation for the lower byte of the index register (H:X) in the CPU08.

Z — Abbreviation for zero, a bit in the condition code register of the CPU08. The CPU08 sets the zero flag when an arithmetic operation, logical operation, or data manipulation produces a result of \$00.

zero — A logic low level, a voltage level approximately equal to the ground voltage (V_{SS}).
